MECHANICAL PROGRESS.

Annealing in Boiling Water.

An English expert on metal working, Prof. W. Mattieu Williams, is writing a series of articles for the *Metallurgical Review*, entitled "Studies in Sheffield." In one of them we find a few paragraps on annealing by immersion in boiling water. We quote as follows: "I will narrate some curious experiments that I commenced when in Sheffield, but have not satisfactorily completed. They were made at the suggestion of Mr. William Bragge, then a managing director of Sir John Brown's works. He had learned that the steel wire strings of piano-fortes are annealed by what appears a very anomalous process, viz., by making the wire red hot and then plunging it into boiling water. Ordinary experience would suggest that this must harden the steel in some degree, but I tried it upon many samples of steel—mild Bessemer steel, sheer steel of different qualities and the hardest old-fashioned Sheffield "pot steel"—and found that in every case, when the operation was properly performed, the steel was remarkably annealed. I compared samples cut from the same bar, one heated and slowly cooled by burying in ashes under a furnace grate, the other by immersion in boiling water, and found that when subjected to bending tests those which had been cooled in the boiling water would bear a more severe degree of flexure without cracking than the pieces which had been more slowly cooled in the ashes. They were not so soft, as tested by the touch of the file, but unquestionably tougher and more reliable when subjected while cold to violent bending blows of a hammer. It was more effectual than any device of 'oil toughening' or slow cooling I have had opportunities of testing.

"Certain precautions are necessary. In the first place the water should be quite at the boiling point and the steel at a bright red heat; and, secondly, the steel should be fairly surrounded by the water. These conditions being fulfilled, the steel remains red hot under water for some time. It is evidently surrounded by a film of vapor and is not in actual contact with the water, which assumes the so-called 'spheroidal state,' continuing in this condition until the metal has cooled considerably. I suspect that the toughening is due to the uniformity of cooling thus effected.

"I commend this method of annealing or toughening to the attention of manufacturers engaged in the production of all kinds of steel that is to be used for purposes where tenacity rather than hardness is demanded."

Self-Fluxing Iron Ore.

In a recent letter Prof. J. P. Kimball, of the Lehigh University, Bethlehem, Pa., announces that he has just made some successful experiments at the Pittsford Furnace, Vermont, in smelting a magnetic iron ore (chateaugay) from the Adirondacks, without any flux whatever; the ore proving, as it synthetically appeared, a self-fluxing ore. The earthy matter consisted of feldspar, quartz, and chlorite, in such proportions as to form a sufficiently acid cinder, between a singulo-silicate and a bi-silicate. The furnace never worked so uniformly, and it made about double the quantity of foundry iron that it ever made before. How much forge iron it will make remains to be proved, but it has hardly sufficient bight for a large burden. The make of foundry pig iron, Nos. 1 and 2, was from 11 to 12 tons in 24 hours. The ore contains only .004 phosphorus; no sulphur. The pig is remarkably tough and soft. The furnace is still running, having blown in on May 2d. This is the first time in this country that any magnetic ore has been recognized as self-fluxing, or at least used as such. In Sweden several well-known magnetites, the so-called *engaendes* ("going alone"), are smelted in the same way. It may be mentioned that an attempt to smelt the above ore in the usual way—raw, and with 25% of limestone—resulted last year, in the hands of the owner, in chilling the furnace. The owner, Mr. Prichard, has since died. The experiment was undertaken for Naylor & Co., the lessees. It may be further stated that the ore was roasted in heaps, merely to render it more porous. Prof. Kimball believes that the iron made will rank with the Swedish steel-irons from similar ores.

SUPERHEATED WATER.—On the railroad connecting Reveil and Marly-le-Roy, France, the experiment of running locomotives with superheated water has, it is said, given very satisfactory results. The water was introduced at a temperature of 180° C., or 356° F., which is equivalent to a pressure of 146 pounds per square inch. If the trial turned out as well as has been alleged, a motive power of this kind may, for many reasons, be adopted with advantage on street railroads.

MANGANESE BRONZE.—Prof. Genti publishes an analysis of a specimen of manganese bronze from a Transylvania factory. It is nearly of the color of brass, is tenacious and ductile under the hammer, and contains sulphur, manganese, copper, zinc, iron, with traces of silica, tin and carbon. The essential ingredients are 15 parts of copper, four of manganese and one of zinc.

Cooling Steel During Hardening.

Joshua Rose writes to the *Polytechnic Review* concerning the behavior of steel during hardening. He describes with minuteness the changes which occur in the metal, and concludes with these suggestions for practice: After an article is dipped to the required depth, it should, if straightness is of importance, be held quite still until reduced to the temperature of the water, because, if taken out before so reduced in temperature, it is especially apt to crack; and it is better to have a deep tank of water, if the body of the metal is great, so that the steel may be dipped slowly downward and become cooled sufficiently rapidly to harden without any lateral movement, except it be after the steel has lost its redness.

When a piece of steel requires to be hardened at one end only, the dipping must be performed with a view to make the graduation from the soft to the hard metal extend over a broad section of metal, for if the junction of the hardened with the soft metal is abrupt, the hardened end is apt to break short off. The method of dipping, therefore, is, in this case, to plunge the end of the steel vertically into the water, to a depth a little more than equal to the depth it requires hardening, and, after holding it still there until it is black hot (that is, as soon as its redness is gone), dip it slowly a little deeper, and then raise it up to the amount of the increased dipping, and slowly immerse again.

When a piece of metal requires hardening and tempering at one part only, we may heat the steel back of the part to be tempered to redness, and dip the article so as to harden the required part, and leave sufficient heat in the contiguous metal to raise the temperature of the hardened part enough to temper it. This plan is always followed in the tempering of lathe and planer tools, flat drills, etc. If, however, the method of dipping is to hold the steel in the water at an even depth after the immersion, the temper-color will be very narrow, while, if the steel is raised and lowered in the water, the color-band will be broad.

NOTES ON WELDING.—Alexander L. Holley read a paper "On Welding" before the late meeting of the American Institute of Mining Engineers. His proposition may be recapitulated as follows: It is certain that perfect welds are made by means of perfect contact due to fusion, and that nearly perfect welds are made by means of such contact as may be got by partial fusion in a non-oxidizing atmosphere or by the mechanical fitting of surfaces, whatever the composition of the iron may be within all known limits. While high temperature is thus the first cause of that mobility which promotes welding, it is also the cause, in an oxidizing atmosphere, of that "burning" which injures both the weld and the iron. Hence, welding in an oxidizing atmosphere must be done at a heat which gives a compromise between imperfect contact due to want of mobility on the one hand, and imperfect contact due to oxidation on the other hand. This heat varies with each different composition of irons. It varies because these compositions change the fusing points of irons, and hence their points of excessive oxidation. Hence, while ingredients such as carbon, phosphorus, copper, etc., positively do not prevent welding under fusion, or in a non-oxidizing atmosphere, it is probable that they impair it in an oxidizing atmosphere, not directly, but only by changing the susceptibility of the iron to oxidation.

A DRY GOODS PALACE CAR.—A correspondent of the *American Manufacturer* says: "The United States Rolling Stock Company, at their shops in Chicago, are getting up what may be called a new departure. This is a palace dry goods car, to be used on railroads by dealers in dry goods, carrying samples along as well as stock to be delivered when sold. The car is 60 feet long, not including platforms at each end, or 60 feet long over all. It is built as light as possible and yet is strong. The construction of the body is very simple, having only two large windows on each side for lighting purposes, but at each end there is to be a state-room for the traveling merchants to occupy nights or days while on the roads. These state-rooms are lighted by three small windows each. The inside of the car was not finished for use, so we cannot tell just how it is to be arranged, but no doubt convenient for the purpose. This car has a sub-cellar, as they call it, between the fore and aft trucks, where may be stored large quantities of domestic goods while in transit, and it has what may be called a mansard roof, or double deck, for light and ventilation, giving it the appearance of a sleeping car—except the finish. This is a new enterprise, and it remains to be seen, upon trial, if it shall prove a successful one."

TREATING BELTS.—A writer in the *Polytechnisches Notizblatt* recommends the application of a good linseed-oil varnish to leathern, hempen or cotton driving belts when they are new, and its repetition every few months while they are in use. This not only tends to preserve them, but also prevents their either stretching or shrinking with variations of temperature, so that they never sit too tight or too slack when at work. When thus treated they remain quite as supple as unvarnished belts, and are less liable to slip. A similar treatment of shoe soles is recommended, as it renders them water-tight.

SCIENTIFIC PROGRESS.

Growth of the Grasshopper.

The report of the United States Entomological Commission, which will soon be published as a volume of the Hayden Survey reports, will give more accurate information than has heretofore been published on the life history of the Rocky Mountain locust. The area in which the locust breeds each year, in greater or less numbers, the commission says, is approximately 300,000 square miles in extent. It is not to be inferred that the locust breeds continuously over the whole of this area each year, for it is to be understood that the locust within its native permanent habitat is essentially migratory in its habits. For a series of years it may deposit its eggs in a given river valley, in some park, or in some favorable area in some of the plains lying about the mountains, yet it may desert its customary breeding-grounds for adjoining regions, or cross a low range of mountains and breed in a more distant valley. Even in this area the true hatching-grounds are for the most part confined to the river bottoms or sunny slopes of uplands, or to the subalpine grassy areas among the mountains, rather than continuously over the more elevated, dry, bleak plains. The area in which the locust breeds lies mainly between longitude 102°, and 114° West of Greenwich, and latitude 53° and 40° North.

From this general breeding-ground the locust is distributed in all direction. The eastern limit of its range is marked by the commission by the following line: "From the southern end of Lake Winnipeg, by way of Lake of the Woods to Pierce county, Wisconsin; thence directly south to Poweshiek county, Iowa; then southwest to Worth county, Missouri; then south through Montgomery county Arkansas, to Houston, Texas, curving westward from this point to Live Oak county, Texas."

In Manitoba the eastern and also the northern limit corresponds very closely with the timber line. Generally the northernmost limit of distribution extends to Fort Pitt, in latitude 53° 40′, and the northern limit of the range of *Caloptenus spretus*, which is the most troublesome species of the locust, extends nearly to the southern limits of the forests which lie partly upon the 53d parallel, but in a greater part between longitude 104° and 114° and above the projected route of the Canadian Pacific railroad. It is probable that other species range north of these limits, but it is not probable that the *spretus* ranges beyond the line of coniferous trees lying along the north shore of the northern branch of the Saskatchewan river. The extreme western limit of the distribution of these locusts is the eastern flank of the Cascade range in Oregon and Washington Territory, and the Sierra Nevada mountains, though in many parts of the country they do not reach a point so far west.

As to the southern limit, the commission lacked data for determining this line satisfactorily. All that its members are able to say in reference to it is that the locusts have been known to cross the Rio Grande at Eagle Pass, and to penetrate a mile and a half into Mexico; that they have been observed in western Texas as far as the settlements have been extended; that they have penetrated New Mexico on the northeast as far as Las Vegas and Fort Union, and they have passed down in the mountain region from Colorado to Taos, and possibly further south.

FILTER PAPER AND METALLIC SOLUTIONS.—At a recent meeting of the English Chemical Society, Mr. T. Bayley read a paper "On the Behavior of Metallic Solutions with Filter Paper, and on the Detection of Cadmium." The author found by quantitative experiments that filter paper has the power of withdrawing silver salts from solution. Some experiments by Mr. Weston prove that the same action takes place between filter paper and mercury salts. The author then investigated the action which takes place when drops of metallic solutions are placed on filter paper. The extent to which the solutions spread being tested by the action of sulphureted hydrogen. In some cases the solution seemed to concentrate itself in the middle of the spot, and in other cases in a ring round the edge of the spot. The degree of dilution, temperature, and the kind of paper used, have an important influence on this phenomenon. Thus a strong solution of cupric sulphate distributes the copper all over the spot; dilute solutions, on the other hand, concentrate the metal in the center. The salts of silver lead and the persalts of mercury, when moderately concentrated, give a wide-water ring containing no metal, while the salts of copper, nickel, cobalt, and especially cadmium, must be much more dilute to present the same appearance. This property of cadmium to spread itself over the whole drop is so marked that it affords an elegant means of detecting it in the presence of metals whose sulphides are black. The diluted solution is dropped upon filter paper, and the spot allowed to extend as far as possible. On exposure to SH_2 a black patch is formed, surrounded by a vivid yellow ring. A solution containing much nickel cobalt or iron in presence of copper, etc., may be examined successively with SH_2 and $S Am_2$ The presence of free acid increases the mobility of copper salts considerably.

Sprouting of Silver and its Cause.

Theo. Flnegger, Assayer St. Louis Smelting Works, writes as follows: Assayers and chemists all know that great care must be taken with the molten silver obtained in assaying for fineness and quantitative determination of same in ores and furnace products, to prevent what is generally termed sprouting of the silver, which is nothing else but a disengagement of oxygen gas, absorbed by the silver while in a highly-heated state, giving rise to the peculiar arborescent appearance observed on the surface of silver after sprouting and endangering thereby a loss of silver. In order to obtain a reliable assay, the greatest caution is therefore necessary to prevent the sprouting, the cause of which is not generally known, but to prove that it is due to the disengagement of oxygen after the act of solidification and not to the contraction of the outer, cooler layers, as some theorists contend, on the inner mass of metal, any one can convince himself by the following small experiment, which will, no doubt, interest many who have witnessed this remarkable behavior of the silver: 50 grammes of pure silver may be taken and placed in a common scorifier with 10 grammes of borax glass, and heated in a muffle to a white heat (over 1,000° C.) for at least half an hour. The experiment will often fail if heated in less time than above stated. After the expiration of the half hour, the scorifier, with contents, can be taken out of the muffle and placed on a brick or some other cool object. The silver can soon be seen to solidify through the clear borax glass which covers it, but the disengagement of the oxygen will not take place immediately after solidification and varies with the degree of heat and other prevailing circumstances. Blowing and disturbing the scorifier must be avoided. The oxygen will gradually show itself by raising the soft and expansible borax glass, forming, in successful experiments, a large bubble about the size of a walnut. The borax glass solidifies in the shape of a small hemisphere, which contains the oxygen. The usual tests for oxygen may now be applied. A match is charred and allowed to glow, the glowing end is suddenly thrust through the thin side of the hemisphere of borax glass, breaking it and exposing to the oxygen the glowing end of the match, which will immediately burst with a bright flare into a flame, proving the presence of either oxygen or nitrous oxide gas. Binoxide of nitrogen will give the final proof of producing red flames, which are conclusive that oxygen and not nitrous oxide gas is present. To this end several of the bubbles obtained on the scorifiers in the above way were burst under water, the escaping gas allowed to ascend into a receiver and then the binoxide of nitrogen introduced by means of a tube, connected with the generating apparatus, containing copper and dilute nitric acid. This neat experiment was first made and successfully repeated in the laboratory of the St. Louis Smelting and Refining Company.

Prof. Henry's Management of the Smithson Trust.

Prof. Youmans, in his obituary of the late Prof. Henry in the *Popular Science Monthly*, makes the following allusion: Having immortalized himself by these brilliant researches of the laboratory, Prof. Henry was called into a more conspicuous sphere of action as the organizer and administrator of a great public enterprise of national scope in connection with the progress of science. John Smithson, an English chemist and physicist, and member of the Royal Society, had left upward of half a million dollars as a trust to the American Government, to be used for "the increase and diffusion of knowledge among men." How this language was to be construed and how the money was to be expended were open questions. The Washington politicians were in favor of spending it on buildings, libraries, and museums to be established at the national capital, and the whole fund would probably have been buried and lost in this way, but for the influence of Prof. Henry. He was appointed, in 1846, as Secretary and principal executive officer of the institution, and at once applied all his energies to rescue the fund from the misdirection that had been given to it, and to devise more efficient means of obtaining the comprehensive object to which it was devoted. As Smithson was a man of science, and an original investigator of that "natural knowledge" which the Royal Society of Great Britain, of which he was a fellow, was founded to promote, Prof. Henry fairly and justly assumed that the intention of the donor was the increase and diffusion of scientific knowledge—increase and augmentation by research and organized systems of observation, and diffusion by means of extended publication. Henry's policy, therefore, was to diminish expenditures upon buildings, libraries, museums, and art-galleries, that the money might be devoted to wider and more legitimate purposes.

THE MARCH OF THE PHYLLOXERA.—A. Reuter's telegram from Madrid to an English exchange, dated May 14th, conveys the unfortunate intelligence that the *Phylloxera vastatrix* has made its appearance in an area of about 2,000 acres in Portugal.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned

California.

AMADOR.

CENTENNIAL COMPANY.—*Ledger*, June 29: This company are pushing ahead with the development of this quartz claim, situated on Dry creek, two miles from Plymouth. The shaft has explored the bowels of the earth to the depth of 250 feet. From the point of striking the ledge, about 50 feet from the surface, the ore body continues unbroken to the bottom. Its average width is five feet, and the whole of the rock, it is said, will touch the paying standard. A small crushing was had at the Bonanza mill, at Drytown, under unfavorable circumstances, which yielded $4 per ton. The regular quarterly meeting of the stockholders will be held next Monday, at which it is probable some definite action will be taken toward the erection or purchase of a mill. The Centennial is among the most flattering prospects on the mother lode in this county.

VOLCANO ITEMS.—R. C. Downs has 200 tons of ore on the dump ready for crushing. This parcel of rock is conceded to be the richest taken out in that section for a long time. Downs says he will be satisfied if it yields $30 per ton. Experts say, however, that if it does not surrender from $80 to $100 per ton, they will be greatly deceived. The water in the Volcano ditch has failed, and the gravel claims aronnd Volcano are at a standstill in consequence. Several of the principal claims were unable to make a clean-up, owing to the unexpected failure of the water supply.

PLYMOUTH.—The Phenix still continues to crush good rock. The old Hite mine yields good rock. All it lacks is capital to work it. The Seaton—there is little doing in regard to this mine; adverse claims being the cause.

CALAVERAS.

GRAVEL MINES.—*Chronicle*, June 29: Times continue exceedingly lively in the gravel mining line in this vicinity. At the Rough Diamond, in Chile gulch, everything is progressing eucouragingly. A full complement of men is employed in the mine, and the mill is kept constantly employed. The yield is in every way satisfactory. Brown & Co., the Tunnel ridge tunnelers, are developing one of the best gravel claims in this section of the county. Operations are unceasingly pushed with first-rate results. The Duryea claim is being worked with more vigor than ever. As many men as can work to advantage are employed, the hatteries never being allowed to "hang up." There is probably no other claim in the middle and southern mines that has yielded so much gold, first and last, as the Duryea, and it has not "suspended payment" yet by any means. Work is being energetically pushed in Vieth's hydraulic. Preparations for a clean-up are now being made preparatory to shifting the hydraulics to another portion of the claim. The harvest of amalgam is expected to be immense. Moser & Co. are pressing things as indefatigably as usual. Piping has been temporarily suspended in the Emerson hydraulic, Happy valley, to permit the running of a tunnel necessary to the proper working of the claim. W. W. Cook, proprietor of the Maison d'Sante hydraulic, is piping in very rich gravel and has got an abundance of it. Work is progressing favorably in a great many other claims in this section, to which we have not space to refer to-day.

SINKING COMPLETED.—The sinking in the Gwin mine for the 1550 level will be completed to-day. The level will be run and stopes opened immediately, alheit there is plenty of rock in the 1400 stopes to keep the mills going. There is every indication that the new level will be an unusually rich oue.

UP COUNTRY JOTS.—Champion rock is now being crushed in Carltou's mill, West Point. Something like 80 tons have heeu hauled to the mill and the work of mining is going on vigorously. The ledge is wide, ore good and the prospects of the mine better than ever. Macheaux, who owns a mine in the suhurhs of West Point, has commenced taking out rock. Prospects flattering. The Billy Williams mine, owned hy Fields & Co., is being steadily worked with good results. The property is a valuable one. At Mosquito, "Butcher John" is working his mine, one of the hest in the upper country, with a good deal of vim. John's mine will make his fortune yet. Rock from the San Joaquin, at Mosquito, owned hy Holmes, crushed in Garland's mill, paid $30 per ton.

EL DORADO.

GOOD PROSPECT.—*Mountain Democrat*, June 29: The Smith Brothers bave opened a promising mine two miles east of Greenwood. At different points the ledge varies from 14 to 50 feet in thickness and has heen traced and prospected for a long distance. During the past winter ana spring, the Smith Brothers have worked a considerahle amount of the quartz in hand mortars, and have run a large amount of the decomposed loose rock through sluices, realizing fine returns. Recently they have made a hargain with H. G. Maltby, formerly engineer of the St. Lawrence mine, hy which they convcy to Malthy one-fourth interest in the mine, in consideration of his erecting a good 10-stamp mill and hoisting works thereon. In pursuance of this hargain Malthy has purchased the mill formerly used at the Cederburg, and will have it up and in working order on the new ground in ahout 12 or 15 days.

THE MILLER MINE.—Moses Miller is doing some work on his own account on this mine, located south of Weber creek, near the defunct town of Weherville, and is obtaining very flat tering results. The ledge is about two feet wide and he has now on the dump some 30 tons of rock, which will average $40 per ton. There is a 10-stamp mill on the ground through which he proposes runuing his rock.

HUMBOLDT.

GOLD FIND.—Ferndale *Enterprise*, June 21: The gold mines discovered on Eel river still cause excited gold seekers to rush in that direction. The har along and in the river for three miles is staked out, and every one is confident that he will strike a honanza on his claim. The gold found lies on top of the bedrock and consists of the very finest particles. The washing shows from 40 to 200 colors to the pan. The largest piece yet found was valued at 10 cents. The work of tunneling has been commenced hy Mr. Bryant, and the prospect is good as far as he has gone. We weut up and looked around upon the diggings, but heing a poor "digger," though very gold hungry, as all editors are, and as all out doors was staked off, we concluded to try to he satisfied with the tripod and to drive the quill a little longer, hoping that some of the gold will float down this way and flood our sanctum.

INYO.

REX MONTIS.—*Imdependent*, June 22: The new ore strike in the winze from the lower level of the Rex Montis cannot be availed of hy reason of foul air and inconvenieuce of economical extraction. Superintendent Hudgins is urging upon the directors the necessity of opening a deeper tunnel level.

NEVADA.

PLANET.—*Transcript*, June 30: The gravel channel in this mine has heen cut with plenty of water. This had heen looked for several weeks, the tunnel had been run in a distance of over 1,100 feet, and an incline had heen raised ahout 160 feet to tap the channel. The Planet has an extensive body of ground, aud there can he no douht of a pay channel running through it, as the "Swamp Angel," adjoining it has pay ground up to its houndary line.

BYRNE CONSOLIDATED MINE.—Work upon the new shaft on the Mohegan ledge, of the Byrne Con. M. Co., on Gold Flat, which was commenced a few days ago, is now down 25 feet. The hoisting machinery will be put up over the shaft sbortly after the 4th of July.

THE SMITH MINE.—Under the new organization, the Smith miue at the Half Mile house is to be opened systematically. Yesterday a new shaft was started, the work upon which will he prosecuted vigorously until a depth of 300 feet is attained, when grouud enough for two years' work will be opened. This mine is now producing good paying rock from the ground already opened.

YUBA RIVER.—*Foothill Tidings*, June 29: This pioneer river mining enterprise is again in motion and in a fair way to show the hidden wealth of the bed of the Yuha. A contract was taken some time since hy Pollard, Nichols and Norton of this place, to put the distracted pumps in order and pump out the mine. This joh, which many supposed impossihle, was accomplished in due time—though hy hard work—and another contract has heen let to the same parties to put in place another pump and and take out various obstructions which the "had luck" last fall left in the way of operating the mine. The present management is going slow, hut hopes to make a sure test of tbe mine this time.

PLACER.

YANKEE JIMS.—*Herald*, June 29: A new company have taken hold of the old Swindle Hill diggings, which always prospected rich hut which cannot be made to pay hy the washing process owing to the cement character of the gravel. The new compauy propose to work the gravel hy mill process, and for this purpose have already commenced to put up a mill, which, with no unforeseen hackset, will he ready for operation in ahout 60 days.

THE SWIFT.—This mine now comes prominently to the front as one of the prospectively rich mines of the Forest Hill Divide. For a couple of years past tunnels have heen running towards the Hidden Treasure mine, with the purpose of striking the gravel in the ancient channel, which the miners are confident of finding.

ON the Excelsior mine, near Ophir, they have struck the ledge—or rather the junction of two ledges which intersect each other—ahout 70 feet down perpendicularly from the surface, and the mine promises very well. Two shifts of men are husily employed night and day.

ABOUT DUTCH FLAT.—On Monday, at the Polar Star mine, a blast of 550 kegs of powder was touched off. It is estimated that it completely broke up 26,000 square yards of gravel. The hydraulic mine at Elmore hill has closed down. The Baker uine has closed down for the season. The last clean-up at this mine was satisfactory to the Superintendent. The water helonging to the company is falling off rapidly, and Mr. Stone telegraphed to the agent to tap the lakes to the extent of 300 inches, in order to keep the Central running. The latter mine will not close until the water is exhausted.

PLUMAS.

JAMISON CITY.—*National*, June 29: Doherty has had his mill, on the Bunker Hill lode, running for more than a week, and is taken out amalgam in satisfactory quantities. He has given to his prospecting a deal of energy and enterprise. Martin Ensley, who is an indefatigable prospector, has lately been trying his hand on Poplar creek, a short distance above the valley, and on Saturday last took out a seven-ounce nugget, together with a fair prospect of fine gold. The nugget contained some quartz, hut after pounding, sold for a hundred and twenty odd dollars.

A NEW BONANZA.—Last Saturday, one of the richest deposits of quartz every found in Plumas, was struck in the upper level of the Bell mine, near Elizabethtown. A cross-drift was hegun last week, and, before reaching the foot-wall, a "chimney" was found, which is far ahead of anything in that line that has heen seen for many a day. The rock is so rich that it is impossihle to find a piece from the vein that does not show free gold, and the vein is two feet wide now and showing hetter every day.

OTHER MINES.—Messrs. Savercool & Co., the proprietors of the Twin Brothers quartz mine, near Ohio valley, are intending to huild a mill on Ohio creek, ahout a mile from the mine. The mill will he run with a burdy-gurdy, 150 feet pressure, and a road will he huilt to the mine, on which to transport the quartz. The Green Mountain mine is doing hctter. A new engine for pumping and hoisting is heing set up and will he ready for use in about 10 days.

SANTA CRUZ.

SILVER PROSPECT.—*Mercury*, June 28: Mr. Meisenheimer, of Lexington, an old miner and prospecter, has discovered and located a gold and silver hearing ledge in the Santa Cruz hills. He assures us the ledge can be traced across the canyons for a distance of three miles; and although showing only a low grade of ore in the croppings, he thinks there is no douht that pay rock can he had at no great depth. Several assays have heen had showiug all the way from $4 to $9 to the ton. From samples of rock shown us from this ledge we should say the mine was well worth prospecting. It is named the Alma gold and silver ledge.

SHASTA.

COPPER CITY.—Reading *Independent*, June 27: The new mill of the Extra mining company, so far as they have yet progressed, is of solid masonry, stone and hrick. The machinery is nearly all in its place, and it is expected that the company will be ready to start up in ahout six weeks. The mill, when completed, will be a first-class one and cost $100,000. The company have commenced digging a ditch, about two miles long, to take water out of Shaw creek, for running their machinery. This, however, will hardly be completed before late in the fall. The company intend at present only to put in 10 stamps, hut provisions have heen made to put in any number of stamps as they may need them hereafter. It is needless to speak of their mine any further than that the ore grows richer and richer as they advance into the hill. This is also true of the Winthrop, Northern Light and Bully Hill mines. The ledges in these four mines average 25 feet in width. Prospecting has heen going on extensively since the warm weather set in, and quite a number of ledges, the croppings of which prospect well, have lately been discovered. Wm. H. Dunn, foreman of the Northern Light mine, Copper City, came down Tucsday last. He brought a specimen of rock taken out the day hefore, which the assayer estimated would go $600 to the ton. Mr. Dunn says there is plenty more in sight just like it.

HAZEL CREEK.—Clark, Bailey & Co., of Soda creek, have commenced to clean up their claim that they have worked on all the winter. The first day they got nine ounces; one piece weighed six onnces. They feel very much encouraged at the result and are satisfied they will do well. Doc. Curl, on Hazel creek, has struck some very rich prospects. Lawson & Hayes have done well in their claim. Lafferty & Co. found a four-ounce piece in their claim last week, and it is paying them about $8 a day to the hand. John Miller has commenced to clean-up and prospects are flattering. Hotalling & Co. have had a great deal of had luck hy losing their dam, but are now doing very well. Our friend Pitt, of Portuguese Flat, says the miners have done very well. There are a great many Chinamen working on the river. Bill Smith, of Dog creek, is doing well at his place, and says most of the claims have paid well.

SISKIYOU.

SCOTT VALLEY.—Yreka *Journal*, June 22: The Oro Fino miue takes the lead here. The mines in the valley were discovered 20 years ago, and a majority of the original locators got broke in trying to develop them. Five years ago other parties hegan to relocate and take out quartz, and the old mill was repaired and a crushing made. The next important transaction was a dividend of a few dollars to each shareholder. Next was the crushing of a few hundred tons, the quartz paying $35 to the ton, and a dividend of a few hundred dollars. There are about 30 claims heing worked, all paying well, and some paying large dividends. The poorest quartz in this district pays $19 to the ton. The French Creek lead is from two to six feet thick, and a true fissure vein. It can be traced for miles, and prospects well the entire length. This camp is rather dull at present. The mines on French creek are owned and worked hy farmers residing in Scott valley, who are husy on their farms at present. If they keep putting in work on the mines for the next year or two, as they have so far, they will make the old French Creek lead pan out gold bullion that will astonish the world. The people of Scott valley have come to the conclusion that they are the proper persons to own and work the mines, so as to pay dividends at home, instead of supporting a class of men who never saw a mine.

THE Lucky Baldwin company started up again last Wednesday, with an extra pump, and the two pumps seem to keep out the water without any extra exertion. Owing to placing the pump too low, the packing was forced out, hut it was soon arranged all right again, and the pumps will he kept going night and day to keep the shaft clear of water. They are now down nearly 20 feet, and expect to strike bedrock inside of 30 feet, when the pay gravel can he prospected.

TUOLUMNE.

JAMESTOWN.—*Independent*, June 29: Harris has nearly finished his 10-stamp mill. It will he in working order in two or three weeks. Quartz mountain is quiet again. They have stopped the mill on the Heslep mine, and discharged all the miners hut four. It is said they will run the mill in the daytime only in a few days. It is reported that the Shawmut mine is going to start up soon.

ABOUT TUTTLETOWN.—There are good mines in this vicinity. There is the Waters mine, for instance, of immense size and carrying much rich ore. Then there's Dharhoure's mine, another big thing. The vein is four to six feet wide, and will average pay enough to make an enterprising man rich, if he has the coin to erect a large mill. To he sure, the rock is of low grade, hut where you can quarry stuff to grind, you need not he very particular as to its richness if you have the means of reducing all you can get out. The Gillis and Carrington, good for as many stamps as there's pickets in a fence. A right good buy for a company with capital to open it. The Galena mine, owned by Burr & Co., is worthy the attention of men of means. The last rock crushed from this claim, which is on the mother lode, yielded upward of $40 per ton. Plenty more of the same sort left, apparently, hut it takes trade dollars to make underground explorations. The Gross mine has many points to engage the attention of an intelligent miner. It is full of metal, and that metal is rich. Not a tenth of the gold can he saved by the ordinary wet-battery process, and yet hy this it will pay $8 per ton, and it has run up to $80.

Nevada.

EUREKA DISTRICT.

MINING NOTES.—*Sentinel*, July 1: Assays from Bullwhacker ore go $85 in silver, and 52% lead. The product of the Tyho Con. for June will crowd $100,000 very closely. From the contractor in the Eureka tunnel, we learn that the face of the tunnel is still in shale, with indications of a change. The change he believes will be an entry into a ledge, and perhaps ore. The new and extensive hoisting works of the Phenix mining company are in course of erection, under the superintendence of Jim Montgomery, who is pushing their completion as fast as possible. Col. T. J. Taylor is shippihg ore from the El Dorado mine to Salt Lake city. The ore is said to be as rich in precious metals as any ever found in the district. The El Dorado is situated on the line of the Eureka tunnel, which will cut it at a depth of about 800 feet from the surface. Rumors have heen current for some days of a strike of rich ore in the Connolly mine. We yesterday learhed, from good authority, that in making a connection in the deep workings, good ore has heen struck, the extent of which is yet unknown. The Geddes & Bertrand, in Secret canyon, is shipping $200 ore to the Phenix (K. K.) furnace. There is said to be a 20-ft breast of this ore in the mine.

THE ALBION MINE.—General Connor and Messrs. Clark and Haskell, yesterday visited the Albion mine. They report work progressing finely, having attained a depth of 240 feet; at the hottom of the shaft the men have struck iron in the shale, indicating close proximity to the contact.

STRIKE IN THE HOOSAC MINE.—We were yesterday shown hy Billy Wermuth, Superintendent, some fine specimens of ore taken from the main shaft. The ore of this mine is a carbonate, and evidently will assay well in the hundreds. Judging from the appearance of the ore which is found in the deepest workings of the mine, we may soon expect the Hoosac to again wheel into the producing mines of the district.

WESTERN NYE.—Grading for the new mill at Grantsville was commenced last week. Everything is lively. A rich strike was made last week hy M. San Pedro in one of his mines located ahout 1,000 feet south of the Alexander. The ore from this new discovery assays as high as $400 per ton. Richard O'Malley has hought an interest in Dutton Fowler's water works, and the citizens of Downeyville will ho supplied with heautifully clear mountain water hy the firm of Fowler & O'Malley. The water is brought a distance of five miles in pipes from the mountain.

HUMBOLDT DISTRICT.

FAIRMOUNT MINE.—*Silver State*, June 29: Col. Buel has employed 18 men to work on the Fairmount mine, recently purchased hy him. Instead of employing Chinese to do outside work, as is frequently done hy mine owners, he gets white men who do not understand mining to do such work at reduced wages. There are plenty of able-hodied men traveling through the

conntry in search of work who can handle shovels and run wheelbarrows, though utterly ignorant of mining, that are willing to work at less wages than are paid practical miners, and it is much better to employ them than Chinamen.

ANTIMONY ORE.—Two car loads of antimouy ore from Graves & Healey's mines, near the Humboldt Salt marsh, were shipped to-day to San Francisco.

REVEILLE DISTRICT.

THE GILA MINE.—*Sentinel*, June 29: During the past week the drift from raise was driven 11 feet, making the total leugth 134 feet. On the 11th inst. struck very fine ore, and have been running on it from that time. The vein is about two feet wide, very regular, and ucarly all soft chloride ore, some of which is very soft and will probably average $200 per ton. This drift is now 150 feet south of the stopes from which ore is being extracted, and is rnuning intn grouud that has never been prospected in the least. From present appearances there is every reason to believe they have a large hody ahead. In the stopes there is no change. The mill is running regularly, with a large amount of ore ahead.

REESE RIVER DISTRICT,

MANHATTAN MINE.—*Reveille*, June 29: During the week ending yesterday mnrning, the mill reduced 137 tons, 1,480 pounds of ore, of the value of $27,961.80. In the Curtis shaft, the ore from the 517 stope shows some improvement on the east side. The winze from this level is passing through some good ore. The 517 west drift has been started again. The 675 stope continues to produce a good quality of nre and shows a large ledge the whole width of the stope. The 675 east drift is in good ore. In the Frost shaft all the ore required is being taken from the 670 stope. The ore chimney shows no sign nf giving out as they work west, and has now attained a width of 300 feet. The 670 west winze and 770 drift have heen connected, which affords good ventilation in the lower level.

TEM PAHUTE DISTRICT.

There are quite a number of miners at work here, some of whom are taking out ore. The great drawback to the camp is the want of a mill, the miners being now compelled to ship their ore to Reveille, a distance of 75 miles, which eutails a large expense. An Eastern party, who have lately visited this district, think well of the mines, some of which it is expected will be sold on their report. Should this so happen, it will, no doubt, lead to a mill being erected near the mines and a more rapid development of the latter.

Arizona.

GLOBE ITEMS.—*Enterprise*, June 25: L. J. Webster on Mouday shipped two bars of silver bullion to San Francisco, weighing 3,150 ounces, and on Friday previous, 3,088 ounces. Two bars still on hand. The Tombstone district, south of this about 125 miles, is represented "way up" in silver ore. A specimen shown here, said to have been brought from that camp, is pimply with native silver.

MINING NOTES.—The Peck mining company's troubles are all settled. L. Bashford has purchased some feet on the Tiger mine for $1,500. The McCrackin mill turned out nearly $83,000 in silver hars, during the month of May, ranging in fineness from 915 to 960. A. G. Hubbard has been chief amalgamator at the mill since February 23d. He may well feel proud of his work. June 2d and June 3d, he melted out 20 bars, worth over $24,000. Wells, Fargo & Co. shipped last mouth $60,000 in silver and $10,000 in gold from Prescott to San Francisco. Bowers and Richards are putting the Senator mill in good shape, and propose reducing ores from the Senator mine soon. The owners of the Emmett mine, situate in the Black Hills district, are contemplating the erection of a 5-stamp mill, and negotiations for the purchase of one in San Francisco are now under consideration.

TUCSON.—This town is alive witb prospectors, miners, capitalists, etc. The specimens they bring in from San Xavier mining camp and Tombstone district are remarkably rich. The latter place is said to have millions lying on the ground in sight. Dozens of prospectors and and miners may be seen each day packing their burros and wagons starting out to work or hunt up claims.

IN THE NORTHWEST.—The Hackberry mill is running and doing well. They have shipped about $50,000 in bullion during the last 30 days. The new hoisting works are now in operation and work on the 430 level is being vigorously pushed, as well as sinking on the main incline. The stopes in the upper levels are showing large bodies of high-grade ore. The ore mills on an average about $150 per ton.

Colorado.

LEADVILLE.—Denver *Tribune*, June 26: Reports are reaching Leadville daily of strikes heing made both north and south, and east and west, enlarging the limits of the carbonate region. This side of the range several locations have heen made on extensive deposits that so far have heen of too low grade to create a rush, though a few resolute prospectors are carefully searching to find richer grades. The camp is in its infancy and it will require another year or two ou its best developed properties to test its lasting qualities, bnt the results so far are simply wonderful. The Gallagher mines, the Iron and Long & Deery, have recently been described in the columns of the *Tribune*, and their past yield and present outlook chronicled. A few facts and figures of another nine less developed and consequently nf smaller aggregate product will exhibit a recnrd that for dull times and in other lines of business, many a man would rejoico to duplicate by a similar investment of capital.

SAN JUAN.—Notwithstanding the long winter and heavy fall of snows, San Juan is putting on snmmer airs in earnest, and our miners are husy at work again nn their valuable properties. A large number of the best mines in San Juan, Ouray and Hinsdale counties have been worked during the past winter, and the result is that thousands of tons nf rich ores are found upon the dump and crowding the ore-houses, where only hnndreds were found last year. No portion of tbe contiuent offers finer opportunities for the investment of capital than this section of Colorado. The deeper our shafts are sunk, and the more capital the miner expeuds the hetter our mines appear, and the richer the ores produced. Silverton is alive, and her energetic miners are busy with pick and drill. Ouray is not behind in tho race, and several smelters are going up, and her mines, amoug the best in the world, are being rapidly developed aud vigorously worked. The San Miguel is attracting a large share of atteution, and its rich gold and silver leads and placers are said to he as rich as any in the State. The mills in the Summit district will probably soon resume work, and if so, we may expect to learn of a large gold product from that rich district. At tbis point husiness is reviving and the smelters are starting up, and we look for a season of progress and prosperity.

Idaho.

MINES ABOUT SILVER CITY.—*Avalanche*, June 22: Despite the Indian disturbances the mines hereabout are heing actively worked and looking well. At the Black Jack, the ledge continues to have the characteristics of an immense bouanza, furnishing indications of a promising future for Florida mountain. During the past three weeks, bullion to the value of $10,000 has been shipped to San Fraucisco, the result of crushings at the Ellmore mill. The mill is now undergoing some repairs and crushing will commence in a few days, teams heing engaged in hauling quartz from the mines. There is great excitement over recent discoveries on the Empire side of War Eagle mountain. On the east side of the Poorman, a ledge has been opened which is yielding ore that will average over $10,000 to the ton. It is full of free gold. On the west side of the Poorman, Mr. Douglas and others are working a claim that is marvelously rich.

GOLD HILL.—Operations here have been delayed by the non-arrival of a pump and two large hoilers intended to he used in connection with the working of the mine. These have been on the way for some time and would have arrived before now hut for the delay caused hy the threatening attitude of the Bannocks. The mine is looking well and has been making a good yield for the past six months. The shaft is down 238 feet and will be sunk still further when the new machinery is put in motion. The recent work on the 100 level shows a rich and productive vein, which pays well aud improves as the descent is made. Altogether the prospects of the Gold hill are unusually encouraging.

Montana.

JEFFERSON, BOULDER AND RADERSBURG.—*New Northwest*, June 22: The Montana Co.'s works at Jefferson are being improved by the addition of a 40-foot reverberatory furnace for desulphurizing ores, and a 10-stamp battery with complete amalgamating works. These additions will he completed hy the first of July, when the works, including concentrator, Bruckner cylinders, reverherators and battery will be started up. The Alta miue, recently purchased hy the company, contains 14 feet of ore at the lowest level, considerable of which is milling ore, and most of which runs from 40 to 150 ounces per ton. The Alta is being worked with a force of twelve men, under Lyman Rowley as foreman, and the main shaft is now down 160 feet. Cole Saunders, the present Superintendent, reports the works capahle of handling the most rebellious ores of the country, and in a short time a graded price-list for the purchase of ores will be issued hy the company, when miners will be supplied with a good home market for all varieties of ore. Work is being prosecuted on a number of other mines in the district, all of which are showing up well. The Gregory, of which I. B. Netter is Superintendent, has a main shaft 300 feet deep, and the ore coming out is said to be rich. Some work is heing done on two exteusions of the Gregory, in one of which Col. W. F. and G. Saunders are interested. Seligman, Lavenberg & Co. are putting up reduction works in Boulder district, to be run on the leaching process. They are going up on Spencer creek, four miles above Capt. Cook's station. There are any number of good lodes in the vicinity of the works, and this move of Lavenherg & Co. has had a reviving effect upon the mining interests of the district. Some 30 or 40 men are working in the Little Boulder placers, not far from Boulder station. The new Keating mill, near Radersburg will be completed in a short time, and the Blacker mill is heing repaired and improved. With hoth these mills running, Radersburg will recover some of its former business activity.

New Mexico.

SHIPMENTS OF COPPER.—*Grant County Herald*, June 15: During the past week Messrs. I. N. Cohen & Co. have received 103,000 pounds nf pig copper from Clifton, Arizona, and during the same time have shipped about 76,000 pounds to the end of the railroad. They have about 27,000 pounds nn hand.

GEORGETOWN.—Mining operations here continue active, shafts are being sunk, tunnels driven and much ore taken out. The mills and furnaces are kept fully employed, and the bullion yield will be larger this season than ever before.

ON THE MIMBRES.—The weather has heen dry so long that we fear that the mills on the Mimbres will not be ahle to run on full time very long, as the river is very low. A good deal of the water is used for irrigating purposes, which will leave the mills without sufficient to run. If it does not rain soon this will he a great drawback to the camp as they have a great deal of nre ahead.

Oregon.

GRANITE CREEK.—*Staats Zeitung*, June 21: The Monumental mine will soon produce results. Large quautities of high grade ore are now being daily extracted hy the work in progress. The tunnel is in 705 feet, and drifts are heing run on the different ledges cut by it. Ledge No. 13. cut at the depth of 300 feet, is rich in antimonial silver ore. An upraise is now under way on this ledge to connect with the shaft, which is sunk a distance of 110 feet, which when completed, will drain and ventilate the mine, and the amount of ore then in sight and prospective will be the basis for the extent and character of the machinery required for its reduction. The Phil Sheridan mine, situate in the same mineral belt, is, under the work now in progress, developing ore that shows from $75 to $550 per ton in silver and $300 in gold. From the prospects of Granite Creek mines it is certain that the miniug industry of Oregon, will soon be extensively prosecuted. No prospects ever ohtained offer better inducements than are now presented. Rightly pursued, mining for the precious metals on this coast ought to be the safest and hest paying industry in which our people could engage. Our mineral territory is rich in this class of deposits and of almost illimitable extent.

News in Brief.

GEN. PLEASANTON is still lecturing ou blue glass.

BALED hay is selling in Petaluma at $6 to $10 per ton.

THERE will be an eclipse of tbe sun visible in this city on July 29th.

GEN. GRANT will return to the United States next spring hy way of India.

THERE are heavy arrivals of wool at Salem, Oregon. Buyers pay 18 cents.

THE river is but 14 feet 6 inches above low-water mark in front of Sacramento.

CHRISTIAN K. ROSS has bad 497 boys exhibited to him as his long-lost son, Charlie.

THE hop vineyards at Puyallup, Washington Territory, are looking exceptionally well.

LAST Saturday, Kate Lorence walked 50 miles in nine hours and 40 minutes at Woodland.

THERE were 305 Chinese passengers on the *Belgic*, which arrived from Hongkong on the 23d ult.

FIRES have occurred in different parts of the State, destroying a good deal of standing and stacked grain.

WARREN LELAND has, according to report, retired from the management of the Palace hotel, in this city.

THE Internal Revenue collections in this city last week amounted to $23,201; total since the first of the year, $965,300.

THE hottest day of the season thus far at Oroville, Butte county, was June 26th, when the thermometer reached 110 degrees.

DURING the month of June, County Clerk Reynolds issued 204 marriage licenses, thereby enriching the County Treasury $408.

THE thermometer at various places in the interior bas been as high as 110° in the shade. Several fatal cases of sunstroke are reported.

THE weather in New York city continues very warm, the thermometer reaching the nineties. Several fatal cases of sunstroke are reported.

PAUL M. MICHELSEN, captain of the sloop *Jill*, plying between Napa and San Francisco, committed suicide by taking strychnine at his residence in Napa.

THE wood shipments at Huffaker's, Nevada, average about 18 carloads shipped to the Comstock per day. Nearly 100 Chinamen are employed as wood-loaders.

C. F. GERMAN, shift boss at the Caledonia mine, fell 1,450 feet in the shaft last Monday and was instantly killed. He was a native of Waukesha, Wisconsin.

THOMAS NOBLE, a son of A. P. Noble, a bright and intelligent boy of 11 years old, died near Berkeley last week, from getting a barley heard in his throat.

EMPEROR FRANCIS JOSEPH closed the Hungarian Diet, Saturday. He took an exceedingly favorable view of relations with foreign powers and the probahility of peace.

SOME Sandwich-island wheat is heing raised this season in Santa Barhara county. It is reported as standing 11 feet high, the stalk heing very light in comparison with its hight.

HEAVY failures are reported in the South Staffordshire iron trade. H. B. Whitehouse & Son, of Bilston, large colliery proprietors and owners of several blast furnaces, have suspended. Liahilities heavy.

SIX hundred visitors arrived at Santa Cruz on Saturday last.

THE Free Labor Exchange furnished 48 persons with employment last week, 34 of them being men.

POLYGAMOUS marriages continue to be frequent in Utah, 110 having been solemnized in one day lately.

THE barrel factory at Tacoma has received an order for 1,000 salmon barrels from New Westminster, B. C.

A PORTION of a tunnel near Scheveliff, Germany, fell lately, burying 27 persons. Seven bodies were recovered.

W. W. STONE, the pioneer merchant of Biggs, Butte county, died, last week, from injuries inflicted hy a runaway team.

THE New York *Sun* reports the veteran editor, James Watson Webb, lying dangerously ill there. He is over 76 years old.

DAVID HELD, a well-known San Francisco merchant, of the firm nf Held Bros. & Co., is dead, from a stroke of paralysis.

JUDGE VENABLES, of Downey City, Los Angeles county, bas 150 acres planted in canary seed, which is in a flourishing condition.

THE total rainfall at Reading, Shasta county, for the seasou has been 60 inches, as against 25.78 inches in the previous year.

RAIN is much needed in nearly all parts of western Oregon. Without it late sow grain in many places will yield little or nothing.

J. W. CARA, aged about 60, a lecturer on astronomy and geology, was found dead a few days since in a stahle at Reno, Nevada.

THERE occurred in this city 98 deaths last week, against 66 for the preceding week, and 102 for the corresponding week of last year.

NOTWITHSTANDING the favorable progress already made, some weeks must elapse before the German Emperor can be removed to the country.

THE spring run of salmon in the Columbia river and also in the Sacramento was a light one, and the canneries have suspended operations till fall.

MICHAEL TOBIN, a United States soldier, has been found guilty of the murder of Peter Alhers, at West Point. The jury recommended executive clemency.

SWARMS of crickets have invaded Paradise Valley, Tuscarora, and other places in northern Nevada. They are a nuisance, hut otherwise have as yet done no harm.

TWO HUNDRED Mormons lately arrived at New York ou their way to Salt Lake. It is estimated that 35,000 have reached that port for the same destination since 1855.

MRS. GEORGE VOORHEES, who was thrown from a carriage in the vicinity of Farmington, San Joaquin county, on Thursday of last week, died at Stockton, on Saturday evening.

DR. DIO LEWIS, the great hygienic teacher, is camping ont with his family and sleeping on the ground in the foothills of the Sierra, now in Nevada county, his health nearly restored.

W. H. VON SCHMIDT, mate of the schooner *Ariel*, which arrived here last week from the South Sea islands, was washed overboard and drowned on the trip. He was a son of Colonel Von Schmidt, the engineer.

A PETITION signed by 581 persons of both sexes is before the Constitutional Convention at Walla Walla asking that the word "male" be left out of the portions of the Constitution which refer to the elective franchise.

BEARS are reported very numerous in Priest valley, Monterey county, coming down from the Gahilan mountains. They have killed over 25 head of cattle, to say nothing of sheep without number, in that locality this season.

ANTELOPE are quite numerous in Siskiyon county, especially on Antelope creek. A gentleman saw a hand of 17 one day, and met others on the next day. Sometimes they run in large bands like droves of sheep, but at this season of the year scatter out with their fawns.

HENRY A. PARR, who arrived from St. John, N. B., has heen arrested in Boston on a charge of murder on board the steamer *Chesapeake*, from New York, for Portland, December 5th, 1863. Parr was one of 17 passeugers who took possession of the *Chesapeake* in the name of the Confederacy, shooting the second engineer and throwing the body overboard.

GOVERNOR HARTRANFT, of Pennsylvania, has appointed Christian K. Ross, father of the kidnapped boy, Master Warden of the port of Philadelphia, at a salary of $2,500 per annum. Mr. Ross had not sought the position, and was taken by surprise when his commission reached him. He needed the place, having spent all his means and much more besides—$80,000 in all, searching for his lost hoy.

Location and Boundaries of Mining Claims.

Upon this subject the New York *Engineering and Mining Journal* has some judicious and well-timed remarks, recommending, in view of the ruinous litigation that has grown out of our former uncertain methods of fixing the exterior limits of mining locations, that we hereafter dispense with our present modes of description, saying nothing about the dips, spurs, angles, courses, strikes, etc., of a lode, and reduce all claims to a square surface location and not to be owned or worked beyond. In further dicussing this subject the *Journal* very justly remarks: "It seems as if it were impossible for any profitable gold or silver mine to escape the blight of a lawsuit, and certainly no greater blessing could be brought to mining interests generally than the enactment of a law that would make it impossible to misinterpret the limits of mining claims. The questions, 'What is a vein?' 'What are the limits of mining claims?' are the bottom of the lawsuits which have ruined so many good mines. The first of these questions has been so enlarged by the Eureka-Richmond decision that an equally perplexing question is now likely to arise in the form of 'What is not a vein?' And, no doubt, efforts will be made to show that any mineral-bearing belt may be thus classed. What the limits of a lode are, will probably become more and more obscure as our knowledge of the ramifications of the ore becomes more and more perfect, until, in a system of fissures such as those in the vicinity of Central Colorado, where the ore is disseminated in the altered country rock, it will be impossible to determine which location should hold a number of intersecting veins.

"We believe it is absolutely impossible to so define the meaning of the term 'lode' or 'vein' as to prevent these endless litigations, and even the rights which are acquired by a patent are very uncertain by reason of our ignorance at times of what constitutes the outcrop or 'apex' of a vein. With the experience of countless lawsuits before us, it seems almost incredible that laws which make such a state of things possible should not have been changed long ago, and especially when the remedy is so simple and so apparent as it is.

"Had our laws been based on the old Spanish mining code, with such modifications only as were necessary from the fact that under Spanish law all minerals belong to the crown, no conflict in titles could possibly have occurred. There seems in fact no way of preventing conflicts of this kind, except by making the boundaries of a claim the limits in every direction to which a mineral deposit may be followed. It will necessarily follow from this that the area taken up must be larger than at present. We would suggest 1,500x900 feet as a sufficient area. The corners should be marked with permanent stone monuments, and the patentee should be entitled to all the minerals found within the lines, to any depth, but could not follow them beyond the same limits. He should be obliged to do a certain amount of bona fide work on his claim every year or every six months, in default of which his rights would cease, and any one else could re-enter the claim. The anomaly of local laws and customs in every district should be abolished, and this one simple and comprehensive law govern in all cases. Of course, it would be impossible to change established locations, but claims located subsequent to the passage of the law, and especially all new mining districts, should be governed by it. It would be impossible to have any conflicts of title, and this most fruitful source of misfortune in mining enterprises would cease. It would then be of no consequence what meaning should be applied to the term, vein or lode, nor would the difficult problem of which lode holds, at intersections and unions of veins, the united vein, any longer trouble anxious mine owners. The problem would be as simple as determining the ownership of a town lot, and the change, though it might be objected to by the lawyers, would be a blessing to miners and mine owners."

NEW DISTRICTS IN MONO COUNTY.—The location of Lake district is on the headwaters of Owen's river, about six miles from the headwaters of the San Joaquin river, and about 24 miles south of Mount Diablo meridian, surrounded by scores of gushing mountain streams, numerous cascades and beautiful lakes (from which latter the district derived its name), thousands of acres of the finest timber ever seen, and green meadows accommodating the horses of 200 prospectors. This is enough, to say nothing about the little insignificant Mammoth mine, which is only 120 feet wide and don't crop out but about 300 feet above everything else in the vicinity. Laurel Hill district is situated about seven miles south of Lake, and bids fair for a mining camp, there having been quite a number of good base metal ledges discovered and located, some of which prospect excellently. Mountain View district is situated about 14 miles south of this place, where but few locations have been recorded as yet. Messrs. Stuhen, Wager and Wilson have discovered a ledge there which they think worth prospecting, and surely they have the capital to prospect or mill and mine with if they can find the indications.—*Correspondence Bodie Standard.*

OFFICIAL returns of the Caribou ore, British Columbia, show it to assay at the average rate of $33 gold per ton.

The Pumelo—A Lusus Naturæ

Written for RURAL PRESS by T. HART HYATT.

The pumela, or *Citrus decumana* of the botanists, is known to but limited extent in California. I have seen specimens raised in this State, and they are generally passed off as huge samples of the orange or lemon. They are called Shaddock in the West Indies from the fact that a Capt. Shaddock, of some merchant ship, brought the first specimens from China or the East Indies. The fruit is generally from double to treble the size of the orange or lemon. I have raised them in China, and had matured fruit on small trees three feet high. But it remains for California to furnish an example of precocity, a most remarkable *lusus naturæ*, such a freak of nature as puts our ideas of the knowledge of the habits and eccentricities of plant creation quite to the non-plus.

The little tree, of which I send you a photograph, was raised by my daughter, Mrs. George North, of Marysville, in this State, from seed planted in February, and was but two months from the time it showed its head above ground until it put forth its first blossom.

The tree is about three inches high, and the blossom, the size and appearance of an ordinary orange blossom. [Our artist has enlarged the plant, so that it is about one and one-half times the natural size.—EDS. PRESS.]

Mrs. North has about 100 trees from seeds planted in a bed at the same time, but none of the others have shown the precocity here exhibited. They are to be transplanted to my daughter's summer home at "Mount Glenwood," Yolo county, about two miles west of the town of Winters, where they have already quite a plantation of orange trees and other semi-tropical plants.

PUMELO IN BLOOM AT TWO MONTHS OLD.

The fruit of the pumelo is coarser than the orange or lemon, but is very juicy and of pleasant flavor. The outside rinds are very thick and coarse and the inner skin very bitter, and has to be taken off carefully when eaten, or it will destroy the pleasant flavor of the fruit. They are used in China, especially by foreigners, to make an excellent kind of tonic bitters. It also makes an excellent conserve. The trees grow to the size of the common orange or lemon, and from present indications are likely to come to bearing maturity in California at a much earlier age than either of the other fruits; and may be cultivated with success, I think, in California. From this precocious little seedling may spring an earlier fruiting variety of the orange family than has ever hitherto been known.

The Marysville *Appeal* of May 30th says: "About the first day of February last, Mrs. George North planted a quantity of pumelo seeds in boxes at her residence, and among the number germinating and coming up was one which is the subject of this item. A few days ago this young seedling, which is about four inches in hight, and the stem or body about the size of wheat straw, showed signs of a fruit bud, and it was watched with much curiosity as to the result. Yesterday morning, however, a full-sized blossom was manifest, with all the fragrance peculiar to the orange. Mr. North removed the seedling to a small earthen pot, and yesterday had a photograph taken of it. It is a remarkable freak and seems to us a burlesque upon the 11 and 12-year-old trees, 14 and 15 feet in hight, without a sign of a blossom."

Vacaville, Cal., June 4th.

The Perennial Streams of Kansas.

The most remarkable fact to an Eastern observer is the permanence of the streams on the great Kansas prairies. Although they do not rise in the mountains, and are not directly fed by the great mountain snow fields, yet it is evident that they are so fed. But a small part of the waters of these broad mountain regions, with 50 feet depth of melting snows, is able to escape in the form of mountain torrents. The pent-up reservoirs pass into the bowels of the earth, and by force of hydrostatic pressure find vent as gushing streams all through the outlying hills and plains for hundreds of miles. These springs are plentiful in Kansas. They are numerous about the sources of our rivers. They are the origin and life of these rivers. They obtain their supplies from the vast snow fields of the broadest chain of mountains in the world, and are not affected by the severest drouths. There is in the driest time more than one hundred horse-power of surplus water passing over the dam at the Star mills, on the Smoky Hill river, at Junction City.

During rainy seasons, which should seemingly cause great floods at the rivers, the water escapes into the subsoil, to a great distance from the channel, and by thus underflowing the valleys their overflow is prevented. Then, as dry weather sets in, this dry subsoil, saturated with water, feeds the rivers and preserves a regular stage of water. These facts have been verified by the rise and fall of wells in the vicinity of the streams, during rains and drouths, and by the permanent rise and fall of wells after the construction of mill-dams. This permeable subsoil, then, may be reckoned as a great hydrostatic balance-wheel, regulating very materially the effects that drouths and rains produce on our Kansas rivers. They are, therefore, more capable and permanent than they could possibly be if fed directly by the mountain torrents, or had no means of storing away the floods of heaven, as they are so copiously but irregularly poured out. No State or country can surpass Central Kansas in the permanence and regularity of its rivers for motive power purposes.—*Junction City (Kansas), Tribune.*

BRINGING IN WATER.—Good progress is being made in constructing the irrigating ditch from the Little Truckee river to Sierra valley. The ditch will carry from 10,000 to 15,000 inches of water. It is expected the water will be into the valley in 90 days. The ditch will bring into cultivation a large area of land that has hitherto lain waste and idle.

Hydraulic Well-Boring.

H. E. Hallet, writes for the *Pacific Rural Press* an account of artesian well-boring on the ranch of W. L. Overhiser, of Stockton, Cal., from which we quote as follows:

The apparatus used for boring these wells was the ingenious "steam well-boring machine," invented by Messrs. Haas & Manning, engineers, residents of Stockton. The machine works something after the fashion of the Diamond drill, and we believe it was from that that the idea was first caught. It has performed admirably wherever tried under favorable circumstances, and is destined to revolutionize the manner of well-boring, reduce the cost to the minimum and place deep wells and plenty of water within the reach of nearly all. It works at a rapid rate in good soil. A well bored in Stockton last summer was sunk 210 feet in four hours and 15 minutes. The gearing for lifting pipe and turning the auger in boring is attached to a derrick 30 feet in hight, whose base is a triangle with sides 15 feet in length. The power used was a 10-horse Wood's engine, running under 40 pounds of steam. In boring deep wells and through hard material, two steam jacks and two anchors are used to steady the derrick. A windlass on the derrick, connected with the engine and controlled by levers, is used to raise and lower the pipe and auger by means of a rope. The anger is turned by means of a system of cogs connected with the engine and pipe by a tall upright shaft and a short horizontal one. The augers are of various diameters according to the bore desired; the one we saw was a hollow cylinder about five feet in length and nine inches in diameter, open at the top and fastened to an iron pipe two and one-half inches in diameter and several feet in length; this is fastened by means of thread and screw to another pipe 14 feet in length and buoyed by a wooden rod, and this in turn is screwed onto a similar pipe, a new pipe being added at every succeeding depth of 14 feet. The rods are six inches in diameter. An iron cap fitting onto the top of the pipe has attached to it a rubber hose of the same diameter as the pipe, the engine pumping water through this hose which supplies the pipe, the water descending to the bottom of the well, softening the material and dissolving it as fast as cut by the auger; the downward pressure of the descending stream of water forces it up again between the wooden rods and the sides of the bore, carrying with it the earth cut out by the auger, flowing from the mouth of the well a thick, muddy stream. The upward flow of the water is strong enough to carry up fine gravel and pebbles, and for coarse gravel or stones, the size of one's fist, a steam siphon is used, forcing up the stones by the exhaust of a vacuum.

When it is desired to shut off the water, a cock is turned in the vacuum chamber and air is pumped instead. The apparatus is completely under the control of the engineer, assisted by two men.

The machine was working down at a moderate rate of speed when we saw it, at the rate of 80 feet per day. We timed two lengths (of 14 feet each), and the time occupied in boring that depth was respectively 28 and 32 minutes; this was near the surface, the material growing much harder as the auger descended. One well had already been bored before our arrival, the depth reaching 133 feet, striking a good stream of water.

Mr. Haas' terms are 50 cents per foot in good soil for any depth, decreasing the cost as compared with hand boring fully 75% and in deep wells much more.

When it is desired to case the wells, the casing is sunk at the same time the well is bored, without raising the pipe or auger. Mr. Overhiser's wells are cased for only the first 14 feet, the material being so hard the rest of the way as not to need it. The cost of casing varies from 60 cents per foot for six inch, to $1.10 per foot for nine inch casing.

THE SUTRO TUNNEL MORTGAGE.—An extension of the mortgage given to McCalmont Bros. & Co., of London, by the Sutro tunnel company, has been filed for record. The document recites that, whereas all the property of the Sutro tunnel company has hitherto been mortgaged to the McCalmont Bros. & Co. to secure the repayment of $124,321.10 advanced to the tunnel company, and all other moneys which may be advanced to it; and whereas other moneys, aggregating altogether $433,965.10, have been advanced to the said company by McCalmont Bros. & Co., the tunnel company agrees that it will, on January 1st, 1891, pay to the said McCalmont Bros. & Co., or their assigns, the said sum of $433,965.10. It also agrees in the meantime, and from January 1st, 1879, to pay interest on the said sum of $433,965.10, at the rate of 12% per annum in semi-annual payments. If the tunnel company shall well and truly pay said interest regularly on the 1st of January and July in each year, McCalmont Bros. & Co. agree not to require payment of the principal before January 1st, 1891; but the property of the tunnel company shall not be released from the obligations of this mortgage until full payment of principal and interest.

THE following is given as the number of Indians in Washington Territory: At Colville, 3,457; at Lummi, 940; at Neeah Bay, 808; at Nisqually and Puyallup, 1,054; at Quineault, 311; at Skokomish, 800; at Talulip, 2,900; at Yakima, 3,650; total, 13,920.

Searching for an Ocean Cable.

Capt. Thomas Stead, commanding the steamship *Professor Morse*, sailed recently from Brooklyn, to search for the Cuba submarine cable. He speaks of his purposes as follows: "The cable is broken," he says, "32 miles from Key West, in the Gulf Stream, where the water is from 450 to 500 fathoms deep—say half a mile. We are going to pick it up, mend it and lay it again. There are two cables between Havana and Key West, one of which stopped working a month or six weeks ago, and we have to find out why it did. It may have been cleanly divided or broken by chafing upon a rocky bottom or from some other violence, and there may have been a minute perforation no bigger than a pin hole through the gutta percha covering reaching the copper wires, and so permitting the water to come in contact with them and destroy the insulation just as perfectly as if the cable had been chopped in two by an axe. The galvanometer simply tells us that the cable has been wounded so as to impair or destroy its usefulness at a certain point, and we must discover what the injury is and how it is to be remedied. How do we clutch it at that depth? Easily enough. We have strong grapnels, four and five pronged, which we send down at the end of this powerful rope—which is made of wire and manila combined—and when, dragging on the bottom, they catch the cable, hoisting it on board is a simple matter. The hoisting rope passes over that drum, between those guides on the bow, over those two drums and is coiled around this enormous drum, which is worked by a donkey engine. If our grapnels catch too near the end, where there is an actual break, the cable will slip off, of course, and then we must go further along the line and grapple for it again. The tension tells us when we have it, and, when we get it on board, we attach the galvanometer, and know at once, how far from us, either way, the break is.

"When we splice the broken ends or attach a length of new cable, we cut one end wedge-shaped and fit the other to receive it, so as to bring in the closest actual contact the ends of the fine copper wires which we then solder firmly together. Then, over that, we put a wrapping of prepared gutta percha, which makes an absolutely impervious covering, taking great care that in doing so no pin holes or bubbles are left to make further trouble. Over that comes the protecting iron wire and its jute servings, the shield that protects the gutta percha. If a new cable has to be laid it is paid out over the stern. Down below are four huge circular tanks, capable of containing together about 300 miles of deep-sea cable. Our cable, you know, varies in size. The 'deep-sea' weighs about 2½ tons, the 'intermediate' about 4½ tons, and the 'shore ends' about 18 tons to the mile. The object in making the shore ends so much the heaviest is to protect the cable as far as possible against injury from ships' anchors and rocks—whichever we use is coiled in those tanks in such a manner as to guard against the possibility of its kinking, and when being paid out is carried up through guides to traveler drums, on aft to a great drum, which it passes twice to give us the power to regulate the tension upon it, by means of brakes, and thence over small drums and through guides again into the sea. It is a work that must be done very carefully, with every precaution against straining, twisting, or looping the cable, and is necessarily slow.

"The principal job of cable laying performed by this vessel since I have been in command was the putting down of 110 miles between Key West and Punta Rassa. That was in comparatively shoal water, probably not more than 10 fathoms on an average. But before she belonged to the present company—the International Ocean Telegraph Company, owning the lines between this country and Havana and the West Indies—I believe she laid some shorter cables. We have done a great deal of repairing, however. Only recently we repaired this same cable, a little way off the Cuba shore, in a depth of 140 fathoms. Mr. Theophilus Smith was then the electrician in charge of the job. This time I take along as electrician Mr. George Keith, manager of the Cienfuegos cable. He has just been out in the same capacity on board the *Investigator*, on an expedition for the repair of the Cienfuegos cable, which was successfully grappled, hauled up and repaired from a depth of 1,500 fathoms. We will take along about 40 men and engage 20 more at Key West."

The *Professor Morse* is an iron 1,000-ton steamship, built at Glasgow especially for this service, at a cost of about $150,000, and was allowed American registry by special Act of Congress. She has four 30-inch cylinder engines, two screws working independently, which enable her to turn around in her own length, and her interior seems a mass of machinery ingeniously adapted to the uses for which she was designed.

More Chrome Iron Ore.—Monday last Mr. Ferguson, of Moro, showed us a sample of chrome iron ore which he claims to be the best yet discovered in the county. He also claims that there is silver in the rock, and thinks from surface indications that a large silver-bearing ledge is somewhere in the neighborhood and only waiting for the lucky finder to tap it.—*South Coast.*

Forty thousand pounds of antimonial ores from the mines of Humboldt county, Nevada, have been brought in to Winnemucca.

Useful Information.

Encouraging Scientific Investigation.

Mr. Uriah A. Boyden, of Boston, Mass., has deposited with the Franklin Institute the sum of $1,000 to be awarded as a premium to "any resident of North America who shall determine by experiment whether all rays of light, and other physical rays, are or are not transmitted with the same velocity." The following conditions have been established for the award of this premium:

1. Any resident of North America, or of the West India islands, may be a competitor for the premium; the southern boundary of Mexico being considered as the southern limit of North America.

2. Each competitor must transmit to the Secretary of the Franklin Institute a memoir, describing in detail the apparatus, the mode of experimenting, and the results; and all memoirs received by him before the 1st of January, 1878, will, as soon as possible after this date, be transmitted to the committee of judges.

3. The board of managers of the Franklin Institute shall, before the 1st of January, 1879, select three citizens of the United States, of competent scientific ability, to whom the memoir shall be referred; and the said judges shall examine the memoirs and report to the Franklin Institute whether, in their opinion, and, if so, which of their memoirs is worthy of the premium. And, on their report, the Franklin Institute shall decide whether the premium shall be awarded as recommended by the judges.

4. Every memoir shall be anonymous, but shall contain some motto or sign by which it can be recognized and designated, and shall be accompanied by a sealed envelope, endorsed on the outside with some motto or sign, and containing the name and address of the author of the memoir. It shall be the duty of the Secretary of the Franklin Institute to keep these envelopes securely and unopened until the judges shall have finished their examination; when, should the judges be of opinion that any one of the memoirs is worthy of the premium, the corresponding envelope shall be opened, and the name of the author communicated to the Institute.

5. Should the judges think proper, they may require the experiments described in any of the memoirs to be repeated in their presence.

6. The memoirs presented for the premium shall become the property of the Franklin Institute, and shall be published as it may direct.

Steel and Iron Car Axles.—At a recent convention of railway men in New York, a report was made by a committee appointed to consider different materials for car axles. The first point considered was the relative duration of iron and steel axles. On this and the other points involved information has been asked from members of the association and others, and the reports of the master mechanics and master car builders have been carefully looked over for points of interest in this connection. A large number of roads are experimenting to a greater or less extent with steel axles, and the performance is being watched. From all experiments there is no doubt that the initial strength of a steel axle is greater than that of an iron one. The disputed point is that of duration of service and ultimate cost of work done. The Pennsylvania railroad is the heaviest consumer of steel axles, and though they show a much longer wear to the one-sixteenth inch on special lots of axles, they have no returns as yet on the general result. The Fort Wayne road claims to have trouble with steel axles breaking. The C., B. & Q. has had some steel axles which have broken, but they were made from the earlier and harder grades of steel. The general summing up seems to be as follows: The steel axles cost twice as much as good iron ones, and it is not yet decided whether they will run twice as long, so as to counterbalance cost, or whether there is the further merit of extra safety to warrant their use.

Export of American Implements.—One of the best markets for American implements for husbandry is South Africa. There we compete with Great Britain as well as in her other colonial possessions in Australia and New South Wales. These British possessions and Germany are the largest markets for American hoes, shovels, forks, etc. The trade centers we have not yet reached direct are Austria, Denmark, the East Indies, China, Italy, Spain, Turkey and Greece. In South America our best markets are the Argentine Republic, Chile, Colombia, Uruguay and Peru. Cuba and Porto Rico use quite a number of our implements, but the Dutch and French West Indies San Domingo and Hayti know nothing of the American plow.

Whitewash.—Good lime slaked with sour milk, and diluted with water till it is about the consistence of ordinary whitewash, is recommended by the *Landwirth* as an excellent coating for woodwork. Fences, rafters, partitions, etc., are effectually protected against the weather for at least 10 years by this application. The casein of the milk in combination with the lime forms a permanent film, which dries so quickly in warm weather that heavy rains falling directly after it has been laid on will scarcely affect the work.

Suggestion on Wood Specimens.—In a library in Warsenstein, near Cassel, in Germany, in the agricultural department, is a novel collection of books. At first glance they appear like rough blocks of wood, but upon closer examination it will be found that each one is a complete history of the particular tree which it represent. From the back of the book the bark has been removed from a space large enough to admit the scientific and common name of the tree. One side is formed from the split wood of the tree, showing its grain and natural fracture. The other shows the wood where worked smooth and varnished. One end shows the grain of the wood as left by the saw, and the other the finely polished wood. On opening the hook one finds the fruit, seeds, leaves and other products of the tree; the moss which usually grows upon its trunk and the insects which feed upon various parts of the tree. To this is added a plainly printed description of the habits, usual location and manner of growth of the tree, all forming a complete history of each kind of timber represented, and in form readily understood by all.

Pigment of the Hair.—Mr. H. C. Sorby, the eminent microscopist, whose name is intimately associated with spectrum analysis, has determined that the coloring matter met with in human hair is due to four quite different and well-characterized pigments. Of these, two, however, serve to modify the tint of the hair to only a very limited extent. The general color is mainly due to a black and a brown-red pigment, both of which can be easily obtained in a separate form and used like water-colors. All the various tints of black, brown, dark and lighter red, and most of the pale tints are easily proved to be due to a variation in the total and relative amount of these two substances. This Mr. Sorby has shown by a series of comparative analyses. These facts have some bearing on ethnology, and afford a probable explanation of certain changes in the color of hair occasionally met with, but not yet fully understood.

Relation of Brain Weight to Mental Ability.—Mr. C. Clapham says, in the last volume of the West Riding Lunatic Asylum reports: "My observations agree with those of Wagner, that weight of brain does not indicate any close relation to intellectual power, and also that aboriginal races are not to be distinguished for smallness of brains. In fact, the ancient Britons, and I may add the ancient Gauls also, were remarkable for good sized, nay even large brains." This statement is borne out by the testimony of the most competent craniologists of the day.

Human Temperature in the Tropics.—We learn from the *Medical Times and Gazette* that Surgeon Major Johnston has made an extensive series of observations in India, on the subject of the normal temperature of the body in the tropics, and has found that, contrary to the general opinion, it is rather lower than the average temperature in the north. In one series of observations he found the mean axillary temperature to be 97.63°, and in another, 97.74°.

Good Health.

Brain Work and Brain Abuse.

When we hear that a man has killed himself by excessive brain work we feel that we should like to have the witnesses in court in order that we might rigidly cross-examine them. What sort of work was it? Was it brain work pure, or was it mixed up with anxiety, worry, and excitement? What were the man's habits? Did he indulge overmuch in what are called stimulants? Did he deprive himself of a just allotment of sleep? If all these questions could be asked and answered we suspect it would be found that the man who is supposed to have died of excessive mental energy died rather of want of fresh air and exercise, of too much fire-water in some form or another, of horrible financial embarrassment, of late hours, and of excitement other than those pure work breeds in the human brain. A distinction is sometimes drawn between imaginative work and intellectual work proper; and the former is said to be the more wearing and the more dangerous. But we suspect there is a fallacy lurking here. Imaginative work, being more exhilarating and producing a greater sense of joy, is no doubt more exciting, but then it necessarily lasts for a shorter time. "Violent delights have violent ends" is as true of imagination as of love. The imagination periodically stops of itself and cannot be made to go on save by those stimulants which, as we have said, help to kill. A man of imagination never shortened his days by allowing his imagination to exercise itself spontaneously; but it is quite conceivable that more than one has done so by artificially calling on it. The imagination should not be so treated. It is too holy a gift and too delicate an instrument to be thus casually instigated to exertion not self-generated. No doubt, at bottom, it is a question of use and abuse, as it is of other forms and capacities of energy. Life is almost certainly not shortened, perhaps a trifle lengthened, and is unquestionably much improved in value, by intellectual vigor; but we fear the people who never think, though their fronto-parietal sutures may ossify early, will continue, as heretofore, to cumber the earth for a greater number of years than they deserve.

Dietetic Experiments.

A carefully noted experience is that recorded in *Nature*, by Dr. T. L. Nichols, an American physician resident in England, who related particulars of a "dietetic experiment" upon himself which he made with a view to solving a difficulty as to the quantity of food per diem which would best sustain health. He began on November 5th, his food being chiefly bread, fruit, milk and vegetables. During the experiment he had taken no flesh meat, wine, beer, spirits, tea, coffee or tobacco. The first week he lived on bread, milk, fruit, and vegetables, the total weight being 3 lbs, 9½ oz., costing 3s. 1d. (about 75 cts.), *i. e.*, a daily average of 8 3-14 oz., costing 5 2-7d.; this was slightly below his standard of 6d. a day. He felt better and clearer and brighter than usual. The second week he studied quality rather than cheapness, his food being "Food of Health," milk and fruit. Total weight, 4 lbs. 4½ oz.; cost, 3s. 8d. (85 cts.); average per diem, 9 5-7 oz., costing 6 2-7d., and nothing could have been better, physiologically, than the effect of that food upon him. His digestion was simply perfect, and the action of the whole system as good as it could be. He then discontinued milk as unnecessary. For the third week the total amounted to 3 lbs, 2 oz., equal to 1s. 9d. (43 cts.), giving an average of 7 1-7 oz. of food, costing only 3d. per day. Milk was not so cheap for food as Gloster, Dutch, and American cheese, because they had to pay for the water it contained. Doctors recommended 2 or 3 lbs. of food daily to repair the waste of the system; but he asserted that the weight of brain atoms and nerve force could not be measured. The food eaten had to be disposed of at great cost of life and strength, and he believed the wisest plan was to eat the smallest quantity that would properly support the body. The fourth week, his food being similar, weighed 3 lbs. 6 oz., costing 1s. 2½d. (30 cts.), giving an average of 8 oz., equal to 2d. per day. He considered 8 oz. the minimum and 12 oz. the maximum quantity of food that should be taken per day. The total weight of his food during the four weeks was 14 lbs 6 oz., costing 9s. 3½d., (about $2.30); average per week, 3 lbs. 9½ oz.; per day, 8 oz., costing per week, 2s. 5d, and per day 4 1-7d. He then added soups, puddings, eggs, etc., and the fifth week his food weighed 3 lbs. 12½ oz., costing 3s. 4d., being at the rate of 8 4-7 oz., at 5 5-7d. (or 12 cts.) per day. For the sixth week the figures were 63 oz., at 2s. 1d, or 9 oz. at 3 4-7d. per day. He had taken the diet without stimulants, and had experienced a constant increase of health and strength and power to work, and his weight had remained at about 12 st. 2 lbs. (170), except that at the end of the fourth week there had been a slight decrease, which had since been recovered.

Fruits in Diseases.

A writer in the *Herald of Health* makes a strong statement regarding the use of ripe fruits in diseases. We cannot say it is not true and yet we should apply the "fruit cure" with some precautions. He says: "There is scarcely a disease to which the human family is heir, but the sufferings therefrom would be greatly relieved by the use of the very fruits which are now so strictly forbidden. Further, many of these diseases would be conducted to a safe termination under the free use of fruits, because of the acids they contain. When our troops were fighting the Seminoles in Florida, many sick with diarrhea and dysentery cured those diseases by stealing from the hospitals into the fields and eating fruits, blackberries especially. Since our very pleasant and profitable excursion of last month, I have sent several children, suffering with cholera infantum and with dysentery, to the peach orchard, with most gratifying results—and where they could not be carried to the orchards to pick and eat the fruit fresh from the trees, I have had the little sufferers fed with sound fruit with equally good results. In typhoid fever, in the treatment of which such extraordinary care is enjoined as regards diet, fruits are not only highly grateful to the patient, but even work very favorable results. A physician who had been sick some weeks with typhoid fever, says his diarrhea was cured by peaches. He says: "I first ate the first half of a large peach, and feeling no ill effects, I ate the other half, then one or two more, and the next day as many as I desired." He adds: "My bowels got better at once, and my recovery was rapid." Since our last meeting, a typhoid fever patient, who had been about three weeks sick, and though imploring, was allowed no diet but beef tea or milk punch, came under my care for a few days. I immediately ordered the free use of peaches and grapes, and the diarrhea at once ceased, and at the end of five days, when I relinquished the care of her, she was convalescent. My impression is, the disease runs a shorter and more favorable course under the free use of fruits than under the usual method of treatment, and I think the use of stimulants rarely required when fruits are freely used. In the treatment of scarlet fever and diphtheria, our summer fruits and many of the vegetables are most useful, and to the best may be added some, or, in fact, any foreign fruits. There is scarcely a disease accompanied with fever, but grapes and bananas may be freely given to the patient. In the treatment of dysentery, I would greatly prefer ripe, sound fruits, peaches especially, to any medicine that can be suggested."

NEW ADVERTISEMENTS.

New York Screw Plates, Dunbam, Carrigan & Co., S. F.

The Week.

Though broken into hy our leading holiday, business during the past week has been fairly active. Among our merchants trade has heen quite as good as usual at this season of the year, the early movement of the wheat crop having imparted to this department of business an amount of vigor not felt in most other callings. That our farmers intend to realize early on their crops is shown by the fact that nearly 100,000 centals of wheat have already been sold, to arrive, the past experience of growers tending to establish the impolicy of holding their cereal for higher prices. With these free sales money will soon he more plentiful in the interior, serving to enliven things there, while a portion of it returning to the city in liquidation of hills due, will have a like effect here also. Only in the matter of real estate is there much cause for complaint, it being difficult to effect sales just now at prices satisfactory to vendors. Still the opportunities for getting hargains here are not numerous, holders, unless forced to do so, heing unwilling to sell at a sacrifice, the ease with which money can he raised on this species of property rendering this class comparatively small.

The heat during the past week has, in many parts of the interior, heen extreme, the thermometer at various places having touched 110° in the shade. As a consequence several cases of sun-stroke have occurred, some of which have proved fatal, a result not usually attending this phenomenon in California. Vast swarms of crickets, and in one or two instances also grasshoppers, have made their appearance in some parts of northern Nevada. As yet these iusects have done no great harm, though it is feared they may do so before disappearing. The week has hrought with it no decisive results from the Indian war in Idaho, though it is expected that something determinate will soon he reached in that quarter.

The 37 deaths reported at the Coroner's office last month are classified as follows: Natural causes, 12; suicide, 10; accidents, 7; murder, 3; stillborn, 2; unknown, 2; starvation, 1.

Surface Boundaries of Quartz Claims.

The only United States law regulating the manner in which mining claims upon the puhlic domain shall he located, and a Government title thereto ohtained, is that passed hy Congress in July, 1866, with its suhsequent amendments, which provides that when the claimant to a mineral vein has made the requisite improvements upon his claim, he may file in the local land office a diagram of the same, so extended laterally or otherwise, as to conform to the local laws, customs and rules of miners, and enter such tract and receive a patent therefor, granting the right to follow the vein or lode with its dips, angles and variations to any depth, although it may enter the land adjoining, which adjoining land shall he sold, suhject to this condition. In construing this act the Commissioner of the General Land Office has decided that where the apex of the lode or vein was within the limits of a claim, the vein may be followed to any depth laterally, though it enter the land adjoining.

Now a case has come up in Colorado calling for adjudication, in which a section of a vein is claimed where through a deflection of its course the apex or croppings ran outside the surface houndaries of the claimant. It seems that in a case of this kind, such section would, under the local customs and regulations of the district and the laws of Colorado, have helonged to the claimant, or at least the latter offered these customs, regulations and laws as evidence on that point. The Supreme Court of that State, however, charged the jury to disregard the same on the ground that any rights so acquired were merged in the United States patent suhsequently ohtained hy the claimant, who the court ruled could not, under the circumstances, hold possession heyond his side lines, as against a party who had subsequently located the adjoining ground and patented it.

In delivering its opinion, the court remarked that the law of Congress in declaring that the claimant of a vein or lode might follow the same *to any depth*, even though its dip carry it into adjoiuing land, had limited the direction in which he might pursue the same heyond his side lines, this heing dowuwards and not in a longitudinal direction. The law presumes that the locator of a claim, before preparing his diagram preliminary to making application for a patent, will have made such developments on the lode as will enahle bim to trace the same and determine its course. As the act does not prescribe that the plat shall be of any particular form, he can so shape thc diagram as to include all parts of the lode within its houndaries, however irregular or tortuous its course. If, for any reason, he neglects to do this, he cannot come to the courts for relief, nor can he seek it under State or Territorial legislation or local rules and customs, since these are of no effect where they come in conflict with the law of Congress. While the phraseology of the act of 1866 is a little obscure, the latter must he construed in accordance with its evident intent, which was to require of the locator due diligence in tracing the course and meanderings of his lode, and to fix the extent to which he might pursue and claim it with as much certitude and exactness as possible. The act contemplates that a lode exists and has been discovered within the houndaries of the tract for which a patent is sought. An unfounded assumption of this fact heiug in contravention of of the law, would, if made to appear, suffice to defeat an application for a patent and probably vitiate one if issued. It is not the purpose of the act to grant surface ground without a discovered lode, this being the principal thing and tbe ground a mere incident.

As the act of 1866 does not require the tract applied for to be of any prescribed shape, so also does it not fix the time within which application for a patent shall he made. The locator may hold his claim and extract the ores therefrom under local, State or Territorial laws and regulations as long as he may deem it expedient to do so, taking all the time necessary to uncover or otherwise trace his lode throughout its entire length. He is just as secure iu its possession under this sort of tenure as any other. After receiving a patent, however, he holds under the United States laws, with the requirements of which he must then comply and to which all these other laws must he suhordinated.

The ahove decision accords, no douht, with the law governing in the case as it evidently does with equity and common sense, and will he sustained should the question be carried to a higher court. It declares against the right of a locator to "swing" or shift his claim to cover a section of a vein lying wholly without its surface houndaries, confining him to that portion that outcrops on the original location.

In view of the conflicting interests that must ever arise out of the plan of allowing locators to follow their lodes heyond the planes drawn vertically through the surface lines hounding their claims, it hecame a serious question whether it would not be politic to adopt the practice that prevailed under the old Spanish rule and which now ohtains in most European mining countries, of confining locators absolutely within their surface lines, as has heen recommended hy Commissioner Raymond and other thoughtful and experienced mining experts. Under the restriction suggested it might hecome expedient to enlarge the area of this class of claims, which might, perhaps, be extended to 1,000 feet in width, confined to 1,500 feet in length, as at present, giving the miner everything found within these limits, hut suffering him to take nothing heyond. An arrangement of this kind would shut out all these complicated questions which are now constantly arising as to the character of geological formatious, lodes, ore bodies, etc., and which have lead to so much costly, vexatious and ruinous litigation.

Iron Smelting in California.

Of all tbe mining and metallurgical industries none seems to he more closely identified with modern civilization than those connected with coal and iron. Iron forms the backhone of every implement in use from the sewing needle to the walking-heam of an ocean steamer; from the jack-knife of the Yankee school hoy to the telegraph wire and the rail that bind together Europe, Asia, and America. Coal is the stored-up energy, the swarthy giant that makes the white man master of the planet. Without these two materials where would he the proud mastery of nature which is the boast of the century?

It has always seemed to us a source of considerahle solicitude for those interested in the permaueut development of a thriving and happy community on this side of tbe Rocky mountains, that the lack of good and ahundant coal fields seemed to make forever impossihle the growth of an iron industry in our midst. Were such not the case we could feel certain that when our gold aud silver mines had heen long exhausted, we should still have a source of permanent prosperity among us. And one, too, that would hring to us not the class of reckless and unprincipled adventurers that are liahle to he attracted hy gold and silver, hut hy men of a different class, who would he permanent additions to our population and whose presence would do much to remove the unsettled feeling that pervades the whole community, whose support depends upon a single industry, especially when of such an uncertain nature as the mining of gold and silver.

Now, we have learned from various sources that there is irou ore in plenty in not only one hut many localities upon this coast, and iron ore of the best quality. How true these statements are we have not, at present, meaus of saying. But we have been assured by many persons that tbese ores have been found free from sulphur and phosphorous in many places. The absence of a good bituminous or anthracite coal has prohahly preveuted the prospecting of these properties. But of late much has heen done in the way of improvement in the smelting of iron which we deem may enahle us to reduce our ores, if we are indeed possessed of them, even without the best of coals.

We publish for this reason on another page a paper on "The Manufacture of Irou Sponge," read hy J. Ireland, M. E., hefore the Iron and Steel Institute in London. As to many of our readers the suhject may be au entirely uew one, we give a brief *resume* of the matter.

As is well known to every one, hy the modern methods of smelting iron, the product of the hlast furnace is not pure malleahle iron, hut a highly carhureted suhstance, known as pig or cast iron, which differs from pure iron in many of its properties, and out of which wrought iron can he obtained only hy removing the carhon and certain other impurities hy some one of several long and costly operations. The idea had often suggested itself to many to interrupt the process hy shortening the furnace so as to ohtain the iron just as it had been reduced to the metallic state, and hefore it had heen changed into the fusible carhuret. In this way the iron would he ohtained in a purer state, hecause not only would it not yet contain carhon, hut other impurities would not yet have entered into it, as the temperature would not he high enough to reduce them. Thus a large amouut of fuel would be saved, and a purer iron produced. This has long been the ohject of many ingenious and costly experiments. For a long time there seemed to he no prospect of success. The iron when so reduced consisted of thread and sponge-like matter, mixed with the gangue of the ore in the most hopeless confusion. The iron being free from carhon was almost infusihle, and so was the ganguc. No means such as fusion would he ahle to separate them. Besides heing so finely divided, the ore coming out of the furnace red hot was as inflammahle as coal, and of course on heing exposed to the air immediately hecame oxidized and useless.

Things were in this condition when thc Siemans Process of "Mixed Steel Preparation" came into vogue and suggested a possihle use for this "iron sponge."

This process consisted in melting down on the hearth of a Siemans-Martin furnace cast-iron, and adding to it wrought-iron scrap. By this means a mixture was produced with less carhon than the cast-iron and more tban the wrought. In other words, a steel could he produced containing any desired amount of carhon. The supply of wrought-iron scrap running short, the price of it rose and the margin of profit hecame so small that the use of iron sponge was suggested and found to he of great value. This in turn has given new impetus to the study of this suhject, and it is prohahle that there is much to he looked for in this directiou in the future.

For hoth the Siemans-Martin furnace and the Blair process good coal is not required, for the gas from any of the ordinary gas producers is capahle of producing the heat required, the most ordinary fuels, as peat, lignite, etc., furnishing the gas.

It will he noticed that Mr. Irelaud, in speaking of his experience with the iron ore of Warora, says: "The condition being that the ore must he reduced by Warora coal. The ore is magnetic, very rich and pure, containing over 70% of metallic iron. The coal, on the other hand, is very poor, heing a hlack lignite, containing ahout 15% of ash and 10% water, hesides a great numher of sulphur pyrites, and it will not coke."

It seems to us that this is worse than many of our California coals. The Mt. Diahlo coal, for example, is even hetter than that. It does not contain more than 10% water and only 5% to 7% of ash, while, of course, it contains, as does the Warora, much iron pyrites.

Mr. I. goes on to say: "Some 20 tons of the Indian ore have been operated upon and iron sponge of uniform and excellent quality produced, part of which has heen made into first-class tool steel and some of it melted in a eupola into pig metal.

"The Indian government are so far satisfied with the experiment that the question of erecting works on this principle for the manufacture of iron and steel in India, is now under consideration hy the council."

We call attention to the last part of the above paper with régard to the subsequent manipulation of the iron sponge. Mr. I., speaking from experience, says it can now he worked up either into wrought iron, steel, or melted down in a cupola to pig iron.

"The first outlay in plant and the wear and tear are reduced to a minimum. To produce 100 tons of the metal per week, the cost of the plant will be about £2,500 — two reducing furnaces, two cupolas, fan or hlower, small engine and boiler, hoist and ore hreaker, heing all that is required."

It seems to us that to say the least here is an opportunity for some of our capitalists who do not know where to find legitimate fields for investing. Let some one who has $20,000 or $30,000, or some half dozen who can command that capital, look up this suhject and if the facts are as we have represented we feel certain that there will have heen gained a source of income not only to themselves hut of permanent henefit to all. We would remark in closing that steel would probably he the most profitahle article of manufacture.

Notices of Recent Patents.

Among the Patents recently ohtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Truss.—Deveron & Lachman, S. F. The improvement consists in forming the pad which presses against the rupture with a flat face and with the sides raised and curved, so as to inclose and hold iu place a dished metallic plate, which forms the hack. On the back of this plate is pivoted a peculiar fastening, so arranged that the waist or hody-helt to support the truss may he attached to it at several different places either way from the center, and, as the fastening is itself pivoted, the pad may accommodate itself to any angle or position that suits the wearer. The dished plate forming the back of the truss has boles in its crown, so that when the rupture presses on the flat surface of the pad and presses it inwards, the air hetween the inuer surface of the pad and plate may be expelled through these holes. As soon as pressure is withdrawn, the elasticity of the pad brings it hack to place, thus pressing the rupture hack. The air then enters the cavity of the truss through the holes in the plate and the pad acts as a cushion on the rupture. At one end of the side of the pad is an opening, through which projects the stud over which the buttock-helt is fastened, and as this huttock-helt holds that end of the truss in position and the waist-helt holds it up, the truss is held securely in place, while at the same time it will accommodate itself to any pressure that may be brought upon it.

Hay Press. — Jacoh Price, San Leandro. The ohject of this invention is to provide a machine for haling hay, in which the hay or straw can he fed continuously into one end of the machine, compressed into one single continuous hale as it passes through the machine, and cut off into proper sized bales at the opposite end of the machine, thus forming a continuously operating hay press. The machine is operated horizontally in order to avoid lifting the hay or straw to any considerahle hight, and the facilitating of feeding it into the end of the machine, although it may he operated in a vertical position if preferred.

Wardrobe or Clothes Guard.—S. F. This invention relates to a novel construction for a clothes guard, which may he hoth fixed and portahle, and it consists in the formation of a prismatic frame having a finished front and door, so that the device may he fitted into the corner of a room and form a complete wardrohe, of which the walls of the room form the sides. A receptahle is formed in the corner part, and is provided with a peculiarly-constructed door, which may be adjusted to fit any form or depth of base hoard which may surround the room.

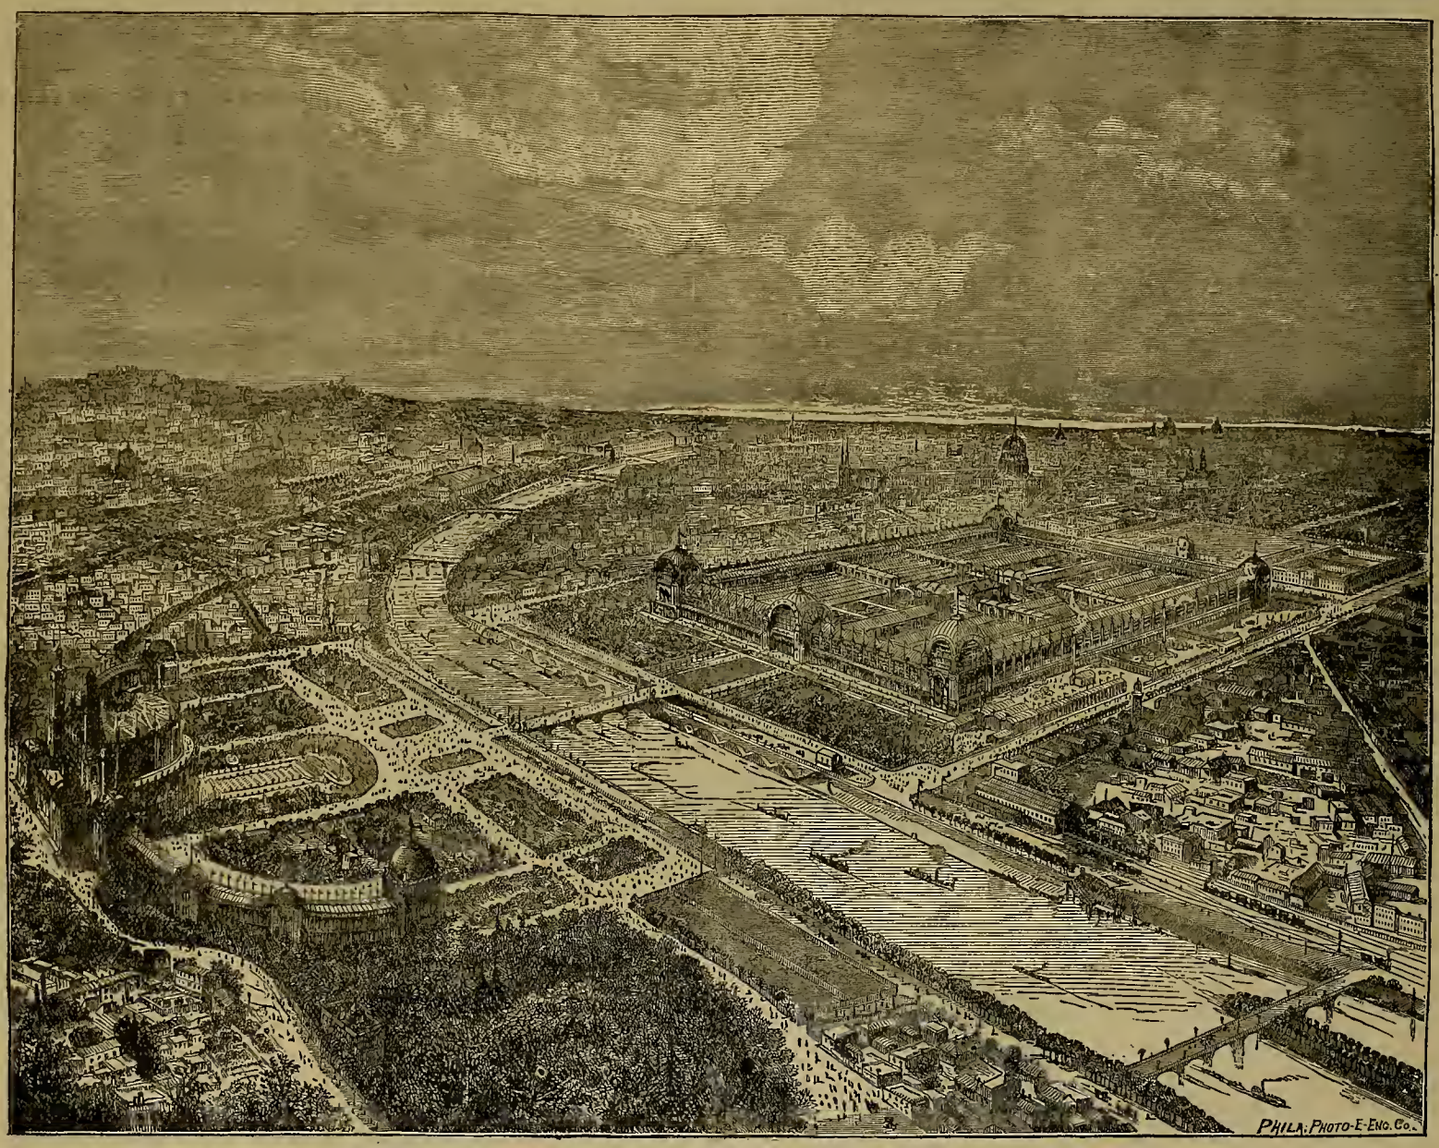
The Paris Exposition.

Our illustration on this page gives a bird's-eye view of the grounds and buildings of the great International exposition which is now in progress at the great city of the French. The reader will note at a glance the magnificent style in which the French people have provided for displaying their industrial strength and achievements. Indeed it calls forth wonder from every student of human progress as he notes the recuperative power which secures such an industrial triumph from a people which has so lately risen from the dust of conquest and invasion. The deeds of the French people are the world's pride and marvel.

It will be seen that the exposition grounds are well within the compass of the rapidly growing city. It will be seen, too, that the plan embraces both level and elevated sites, with the river Seine running between them. The exposition buildings consist principally of colonnade extending along the wings of the palace there is a fine view of the park as well as of the exhibition building, and of the city itself. On the outside the Palace of the Trocadero is adorned by a cascade of water falling from a hight of 26 or 30 feet into an ornamental lake, round which extend the elegantly laid-out grounds, in which figure many striking sculptures by well-known artists. Concerts and other entertainments will be held in the Trocadero.

The open space between the Seine and the Trocadero palace is about 500 yards in length, lying along a steep hillside, sloping toward the river. The hillside is steep—so steep, in fact, that a horse draws a cab containing two persons up the sloping streets adjoining with much labor. The tract has been converted into a charming and varied landscape, ornamented with a number of curious buildings, and containing delightful gardens, fountains and cascades. Among the curious buildings, some are of Japanese and Chinese construction, and some are model cottages of Sweden, Norway, Switzerland, Egypt and Turkey. One structure is the divided by two galleries extending between them and their whole length. At the four corners of the rectangle rise higher pavilions, surrounded by domes, which reach to a hight of 132 feet, and are constructed in a semi-Oriental style that is decidedly pleasing. In front of it are beds of rhododendrons, grass plots, statues, fountains and conservatories. The terrace is 280 meters in length by 20 in width. At intervals are placed gigantic sculptures, symbolizing the principal participators in the exhibition.

France has reserved for herself a large part of the space provided for exhibits in the Champ de Mars building. She occupies one-half of the vast edifice—all the galleries on the left of the central portal, besides a large part of the middle gallery are set apart for fine arts. On the right side, the visitor on entering will come upon the English exhibit. Next to France, England occupies the largest space—one-eighth of the palace—allotted to any nation. Next to England in the main building comes the United States. The space allotted to the United States is about one-fifth of that occupied by Great Britain. Although our exhibitors were



BIRD'S-EYE VIEW OF THE BUILDINGS AND GROUNDS OF THE PARIS EXPOSITION OF 1878.

two vast edifices, both newly erected; the one located on the hights of Trocadero and the other in Champ de Mars. The building on the hill of the Trocadero is to be a permanent palace and is in many respects a remarkable edifice. It is placed on the crest of the hill, and looks to the northward over the new suburb springing up on the west side of Paris, and in the southerly direction down on the river and the Champ de Mars. On the left side of the engraving is seen the building on the Trocadero. In the center, rising above a grand portal about 100 feet wide, is a pavilion, or grand dome, with a tower on each side reaching up about 250 feet. Flanking the rotunda are galleries reaching out in horse-shoe shape toward the river, the frontage being 1,600 feet. The rotunda is an immense structure, containing the largest concert hall in the world, with a capacity of seating 6,000 or 8,000 persons. The towers form the highest points in Paris. They are furnished with lifts worked by hydraulic power for the elevation of visitors by the hundred or two at a time. From the top of the towers the view takes in the Valley of the Seine for miles on each side, and every prominent building in the city is easily distinguishable. The grounds around are beautifully laid out, and from the Algerian pavilion, of the purest Arabian architecture.

Below these interesting structures on the hillside runs the Seine river, separating the Trocadero from the Champ de Mars. This river, instead of being an interruption to the plan of exhibition, has been made one of its most picturesque attractions. The whole length of it between the Trocadero side and the Champ de Mars has been appropriated by Commissioner General Krantz, and used exclusively for the purposes of the exhibition. The Pont de Jena, which connects the two banks of the river, has been widened and inclosed for a crossing place, and it looks as if it had been newly built for the occasion.

Crossing the bridge we come to the Champ de Mars, the main grounds of the exposition, shown in the large enclosure in the center of the engraving. The Champ de Mars building is an immense temporary structure, quadrangular in form. It is the main exposition building, and is more than 2,000 feet in length by 1,000 in width. The east and west fronts having long machine galleries measuring 2,310 by 120 feet. The principal front is located parallel to the Seine, 700 feet from the quay. The general plan of the building includes three pavilions, among the last in the field and have been hampered by the meager appropriations of Congress, our department is among those which were the first ready. The quality of the exhibit is reported as quite creditable, and in some particulars as beyond competition. Our contributions are arranged in eight groups, which may be briefly indicated as follows: Works of Art, Educational Apparatus, Furniture and Accessories, Textile Fabrics, Mining Industries and Products, Mechanical Industries and Apparatus, Food Products and Agricultural Implements.

A CORRECTION.—In an article entitled "New Almaden and Guadalupe," in the issue of May 25th, 1878, we made the statement that the walls of the old condensers of the Guadalupe absorbed 6,000 flasks of quicksilver before any was obtained from them. Mr. B. B. Thayer informs us that the correct figures are 600, and not 6,000.

A BIG deposit of ice has been found in the Olympic mountains, Washington Territory, and the *Dispatch* says it can be brought to Seattle at a cost of $5 per ton. Ice now costs $80 per ton there.

ACTION TO SET ASIDE LAND PATENTS.—A dispatch from Washington dated June 29th contains the following item of news on public land matters: "Secretary Schurz to-day officially requested Attorney-General Devens to institute proceedings against the Central Pacific Railroad Company to set aside the patents issued to that Company for about 20,000 acres of land situated within the claimed limits of the Manuel Dias grant, in Marysville land district. This grant was rejected by the Supreme Court in March, 1873. The lands were patented to the railroad Company under dates of March, 1872, March, 1875, and December, 1875. Secretary Schurz holds, that under the principles announced by the Supreme Court in the case of Newhall vs. Sanger, these lands, being within the limits of a private grant, were excepted from the operation of the railroad grant, and patents were issued for them erroneously, without authority of law. He also invites the Attorney-General's attention to the decision of Secretary Chandler in the California case of J. W. Harbison and others, in which it was held that the patents for lands then in question were erroneously issued, and the Commissioner of the General Land Office was instructed, July 12th, 1876, to call upon the Central Pacific Railroad Company to return them. Schurz informs the Attorney-General that this request has not been complied with."

METEOROLOGICAL SUMMARY FOR JUNE.—The report of the U. S. Signal Service officer, of San Francisco, for the month of June is summarized as follows: The mean hight of barometer for the month was 29.91; mean temperature, 58.2; mean humidity, 73.02; prevailing winds, southwest; highest barometer, 30.148; lowest, 29.745; highest temperature, 73°; lowest, 52°; monthly range, 22; greatest velocity of wind, 34 miles per hour; total number of miles traveled by wind, 8,711; total rainfall, .01 inches. Rainfall in June during former years: 1872, .04 inches; 1873, .02 inches; 1874, .14 inches; 1875, 1.02 inches; 1876, .04 inches; 1877, .04 inches.

THE Southern express from Philadelphia was thrown from the track near Claymont, Del., on the first inst., and the engineer and fireman were killed.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME St., N.E.Cor. Pine, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventious and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

SAN FRANCISCO,

No. 218 Sansome Street.

It is not surpassed by any dining house in the city The saloon is new, commodious, elegant and comfortable, and all visitors to San Francisco, who wish good food well prepared and properly presented, at reasonable prices, should try the "Palace." Being new, it is fitted up with the latest and best approved cooking apparatus and other conveniences for patrons.

Tip-top Dinners, 50 Cents,

Are given from 5 to 8 o'clock P. M. It will pay yourself and friends, too,) to go considerably out of your way to visit and patronize this first-class restaurant.

J. M. WEBSTER,
Proprietor.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco.

The "San Francisco Law Journal."

Published weekly, in 8vo size—like the California Reports—contains ALL the decisions of the California Supreme Court, soon as rendered, with syllabus and statements of facts; and also, important decisions of other courts of last resort. Two volumes each year, commencing September first and March first, with full index, so it can be nicely and cheaply bound.

Price, only $6.50 per year, or $3.50 for six months, strictly in advance. We print a "Legal Directory" on the *Journal* cover of lawyers' address cards, kept corrected for the year, for $3, or six months, $2 in advance. *Journal* and card both one year in advance, $9. Six months, both, $5. Remit by postal order or registered letter, specifying what date or number to begin. Back numbers furnished. Single numbers 25 cents each. Legal briefs and transcripts our specialty. Address

BAGGETT, SCOFIELD & CO.,
Washington St., Cor. Montgomery, S. F.

LAND! BOUNTY!! PENSIONS!!! PATENTS!

Do you want to buy, sell or exchange lands or other property in any part of the U. S. or Canadas? Are you a Soldier or Sailor, in want of a Patent? Why not obtain more Bounty or Pension? Do you want to locate Government or State Lands without settlement? Why not? When I have the well-known Approved Soldiers Additional Homesteads, under seal of the General Land Office, and that can be located without settlement, upon any Government $1.25 or $2.50 lands, subject to homestead. The Sioux Half-Breed Scrip, for location upon unsurveyed lands.

Land Warrants and Scrip of all Kinds

For cash, or part on time. Good title given or no pay. Have you any lands with an imperfect title to sell, or choice vacant lands you know of which could be located to advantage; or claims not lawfully held, which we could contest. Let me hear from you in full, and I will do my best to inform you what is to your advantage.

I will mail you a circular explaining all, and a copy of the new Pension Law. Address, (plainly)

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:

One man, per day	$ 3 50
One man, per day	3 00
Wood, 1¼ cords at $3	7 00
Cost of 20 tons	$13 50
Cost of one ton	67½

From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address:

JUDGE WM. WEBSTER, Paymaster Mine, Reno, Nev.
LEWIS CHALMERS, Manager Exchequer and IXL Mines, Silver Mountain, Cal.
J. S. CONE, Vice-President Tehama County Bank, Red Bluff, Cal.
R. H. CAMPBELL, Superintendent Afterthought Mine, Redding, Shasta County, Cal.

For further information, apply to

D. J. O'HARRA, Reno, Nevada.

GREAT ENTERPRISE!

—THE—

Sierra Flume & Lumber Co.

Have over 100,000 Acres of

SUGAR PINE, YELLOW PINE, SPRUCE

Fir and Cedar Lands,

10 Saw Mills, 3 Planing Mills, 1 Sash and Door Factory,

149 Miles V Flumes,
10 Miles Tramway,
157 Miles Telegraph Line,
13 Telegraph Stations,

Employ 475 Men and 550 Oxen & Horses.

The Sugar Pine is unsurpassed in quality, and the whole Coast can be supplied.

The Yellow Pine is firm, fine grained and superior to any other hard Pine for Flooring, Stepping, etc.

The Spruce has great strength, durable when exposed, and especially adapted to Bridge and Ship Building, while the Fir and Cedar are as valuable for a great variety of purposes.

Last year thirty millions of feet were cut and the estimate for 1877 is fifty millions; fifteen millions are now on hand, thoroughly seasoned by the hot climate of Red Bluff and Chico.

Large orders can be filled on a days' notice for all kinds of

BUILDING MATERIALS,

Rough or dressed dry, by which elegant and substantial work may be accomplished without delay at the usual cost for green lumber.

Orders for the interior filled at less than San Francisco prices and freights.

DOORS, SASH and BLINDS always on hand in large quantities. Address

SIERRA FLUME AND LUMBER CO.

Mining Share Market.

The adjournment, last Saturday, of the two principal Boards over to the 8th inst., left but a fragment of the week for stock transactions, aud, during this, no great amouut of husiness was done. The "Little Board," with the exception of the "Fourth," continued operations in a puhlic way, and on Monday an attempt was made to dispose of shares at auction. This last proved wholly a failure, the entire business done during the week having heen very limited, nor did prices vary mnch from rates prevailing for some days before. After vacation it is expected dealers will take hold with renewed energy, and that, under the developments now considered imminent in the Comstock, a more lively market will early obtain. Going to press this week one day in advance of our usual time, we are without our customary Washoe summary. We are advised, however, that the deep explorations in progress along the Comstock have heen pushed with wontcd diligence, all the leading mines, from Overman to Utah, continuing the scenes of unceasing and energetic work. Along the Gold canyon arm of the mother lode, operations have also been kept persistently goiug, while the "header" of the great Sutro tunnel has been advanced another 50 feet nearer its objective point, having already passed beyond the east wall of the Comstock belt. With the incoming week, it is hoped that further revelations will be made touching the mysteries of Julia and Ophir, each of which the optionists feel certain have heen made the receptacles of a great metallic wealth.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

Mammoth Bar G. M. Co.—June 29: Capital stock, $10,0000,000. Directors—William P. Dewey, George L. Peahody, A. H. Haggadon, R. Shoemaker and James M. Seawall.

Folsom G. M. Co.—Juue 29: Capital stock, $6,000,000. Directors—Cabel H. Maddox, Benjamin Flint, C. P. Jenkham, Albert Heath and C. E. Buckingham,

Price and Davis M. Co.—July 1: Capital stock, $10,000,000. Directors—George W. Hopkins, J. H. H. Williams, Clinton Gurnee, E. F. Stone and N. G. Andrews.

What Makes a Good Expert.—The tests of scientific expertuess, says Dr. Beard in the *Popular Science Monthly*, are: Distrust of the senses; the recognition of the relation of inductiou to deduction; avoidauce of all sources of error, in observation, experiment, or reasoning; the appreciation of the relative importance and non-importance of real or supposed facts; the ability to distinguish reality and its semhlance, especially between the subjective and the objective; and, wbat indeed follows from the other three tests, the maintenance of mental equilibrium during experimental researches. The reputation of an expert is acquired primarily through other experts, and secoudarily through the judgment of mankind. Expertness has its various degrees; there are experts, and experts, and experts: the highest experts are the originators, the explorers, the pioneers, the founders, the creators of science; the lowest experts are the followers, the gleaners, the treasurers, the curators of what others have discovered, and who simply repeat and retain the experiments of genius. The highest experts—the Newtons and Galileos, the Harveys and Jenners of science—must stand at first alone, with no other expert at hand, hy which to estimate their relative hights and strength; it is their necessity and their glory to educate experts, hy whom their own merits are to he tested; they must create the standard by which they are to he judged; their critics will he their own offspring.

The Sioux Indians, of Montana, are getting hold: A few days since two of them meeting W. C. Gillette, an old settler, compelled him to give up his saddle and a valuable gold watch, under a threat of taking his life.

The Eureka Consolidated mining company has levied assessmeuts amounting to $100,000, and dishursed in dividends to its shareholders a sum total of $2,350,000.

Patents and Inventions.

List of U. S. Patents Issued to Pacific Coast Inventors.

[From Official Reports for the Mining and Scientific Press, Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

By Special Dispatch from Washington, D. C.

Week Ending June 18th.

Trace and Pad Buckles.—George E. Bales, Seattle, Washington Ter.

Book Holders.—James D. Brown, Suisin City, Cal.

Trusses.—Duncan Deveron and Herman Lackmann, S. F.

Wardrobes.—Michael Doyle, S. F.

Vineyard Plows.—Milton Ross, San Jose, Cal.

Seed Sowers.—William A. Horrall and Joseph J. Verckler, Chico, Cal.

Ammonia or Ether Machines.—Eugene Moreau and Jas. W. Haggerty, S. F.

Trademarks.

Carbonate of Soda.—Charles R. Burrage, S. F.

Cream of Tartar.—Charles R. Burrage, S. F.

Medicinal Compound.—Charles R. Burrage, S. F.

Coal Oil.—John E. Miles, S. F.

Prospecting for Coal.

As prospecting for coal is continually in progress on this coast, the following method in vogue in Pennsylvania, as described in the *Coal Trade Journal*, may he of value: The ordinary tools of the borer consist of a set of iron rods from one to one and one-half inches in diameter, half a dozen drills or chisels, a pump or sludger, a windlass and ropes, a pair of handles, and a set of wrenches. The rods are usually from 8 to 16 feet in length and are screwed together hy pin and socket joints. A well is sunk down to solid material, if solid ground can he reached within 10 or 15 feet of the surface, and a wooden conductor is lowered and placed in a perfectly perpendicular position—the upper end reaching to the surface. If firm material cannot he reached without sinking to the depth of 20 feet or more, the hore hole is generally started without sinking any preliminary shaft. A large "hit" (sometimes an augur is used), cuts a hole in the clay, and when the material will no longer stand, a gas pipe is lowered. The clay hit is now reduced in size to work inside of this pipe, and as the hole progresses, the pipe is driven down hy the aid of a battering ram. In stony ground it is often a trying and tedious undertaking to fit the pipe down to the solid rock. The drill hole is generally made from two and one-half to three inches in diameter. In favorable material about two feet are cut before the tools are withdrawn to clean the hole, and if necessary, renew the chisel. The tools are suspended on the end of a spring pole, aud the drillers strike into the ground hy bearing on the handles, making a rotary motion at each blow, in order to maintain a round hole. About 13 hlows are given to a circuit. As the hole deepens the progress of sinking becomes slower, owing to the greater time required in raising and loweriug the tools. The debris of the hole is raised hy a pump, and is carefully examined, as it is poured on the ground. The thickness of the different kinds of material passed through is entered in a note hook or journal. When approaching coal, unusual care and vigilance are exercised, hy the horers, the tools heing raised every six or eight inches. An experienced horer can generally tell the moment he strikes coal, by the altered sound of the chisel, and hy the increased speed of cutting. When coal is tapped, the tools are withdrawn, and the hole thoroughly cleaned. The rods, on heing let down, are carefully marked, and after six inches or a foot has been cut into the coal, are again withdrawn, and the pump sent down for the horings, which, on heing raised, undergo the most minutc examination, to determine the character of the coal.

Gold in Osceola.—A solid gold nugget, worth something over $50, says the Ward *Reflex*, was shown us, on Saturday, hy J. W. Rounds, taken from Dry gulch, in the neighborhood of Osceola. We are told this is the first nugget of any consequence that has been taken from Dry gulch. It presents the appearance of having been melted and afterwards submitted to the action of water for an indefinite period. Osceola will certainly, sooner or later, he the center of an excitement that will compare favorahly with many that have attracted the attention of this coast. This district lies in eastern Nevada, near the Utah line.

The Winnemucca *Silver State* says: The owners of the Tiger mine, in Sacramento canyon, are putting up a five-stamp mill on the property. The ledge is developed to a depth of 150 feet from the surface and is well defined and quite rich in gold as far as prospected.

Woodward's Gardens were never more attractive than at present. Besides three lions already mentioned, six monster living alligators, several iguanas and a hoa-constrictor have just been added. New stars are constantly engaged for the Pavilion exercises. Rates of admission as usual.

Examine the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $50,533,429.04. Lewis C. Grover, President; L. Spencer Cohle, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

Model Maker and Machinist.—I. A. Heald, No 514 Commercial St., San Francisco, (fourth floor).

GENERAL MERCHANDISE.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sen through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where he principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official noticee of their companies in this paper, as the cheapest appropriate medium for the same.

Gover Mining & Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-fourth day of May, 1878, an assessment (No. 36,) of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in gold coin or legal currency of the United States, to the Secretary, at the office of the Company, Room 8, No. 402 Front Street, San Francisco, Cal.

Any stock upon which said assessment shall remain unpaid, on Wednesday, July tenth, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the first day of August, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. O. WILSON, Sec'y.
Office, Room 8, No. 402 Front Street, San Francisco, Cal

Seaton Mining Company.—Location of principal place of husiness, San Francisco, Cal. Location of works, Drytown Mining District, Amador County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-sixth day of June, 1878, an assessment, (No. 14,) of seventy-five (875) dollars per share was levied upon the capital stock of the corporation, paysble immediately in U. S gold coin, to the Secretary, at the office of the Company, Room No. 58, Nevada Block, northwest corner Pine and Montgomery Streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of July, 1878, will be delinquent and advertised for sale at public auction, and unless paymeut is made before, will be sold on Wednesday, the twenty-first day of August, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

JOEL F. LIGHTNER, Sec'y.
Office, Room No. 58, Nevada Block, northwest corner of Pine and Montgomery Streets, San Francisco, Cal.

Summit Mining Company.—Location of Principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 3,) levied on the third (3) day of May, A. D., 1878, the several amounts set opposite the names of the respective shareholders, as follows:

AMERICAN

WATCHES!!

BUY THE BEST.

The New York Watches,

Made in Springfield, Mass.

Full Plate Movements Have the Following Advantages:

The winding parts of the Watch are superior to any in use in a full plate movement, for the following reasons:

They are attached to the barrel bridge on the top plate, so that in case of repairs any piece of winding part can be taken without removing the movement from the case or taking off the dial.

There is also an improvement in the manner of letting down the main spring, which is done by means of a pin attached to the click.

The winding parts are so arranged that there is hardly a possibility of either the ratchet, click, or click-spring breaking. There is a turning made in which to place the click, so that when the strain comes on it, the back rests against the solid plate, thus making it impossible for it to break.

In case the main spring breaks, the barrel can be taken out without disturbing any other part of the Watch.

The train of the Watch is run into the solid pillar plate and not into bridges screwed to the plate, as is usual; this avoids all danger of any alterations in the depthing taking place.

The hair spring stud is attached to the balance cock in such a manner that it can always be adjusted to its original position.

The escapement is the most improved form of a lever escapement now in use.

The manufacturers claim an advantage in our potence, as it is not liable to change its position and disarrange the escapement, as is often the case in full plate Watches; also on the bearing for the lower center wheel pivot, the plate being so constructed as to allow a long bearing.

The movement can be taken down and put up with less trouble than any other movement made in the United States, showing it to be the most perfect in simplicity and durability.

Sold at the lowest rates possible for perfect time-keepers, by

From A Patentee.

SAN FRANCISCO, July 1st, 1878.

MESSRS. DEWEY & CO., PATENT SOLICITORS.—*Gentlemen:*—On the first of June I made application for Letters Patent for an improvement on a fire-resisting and non-conducting compound through your Patent Agency, and was agreeably surprised to receive official notice that the patent had been allowed on the 15th day of June, in the unprecedented short time of fifteen days from the time it left here.

This is the seventh patent which I have procured through your Agency, entire satisfaction being given in each case, and I shall take great pleasure in recommending your firm for reliability and promptness to all inventors with whom I may come in contact.

I have now two more cases ready, and shall make the application through your Agency.

Yours Truly, GEO. R. EVANS.

GIANT POWDER

MANUFACTURED UNDER A. NOBELS' ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS,

Nos. ONE, TWO and THREE.

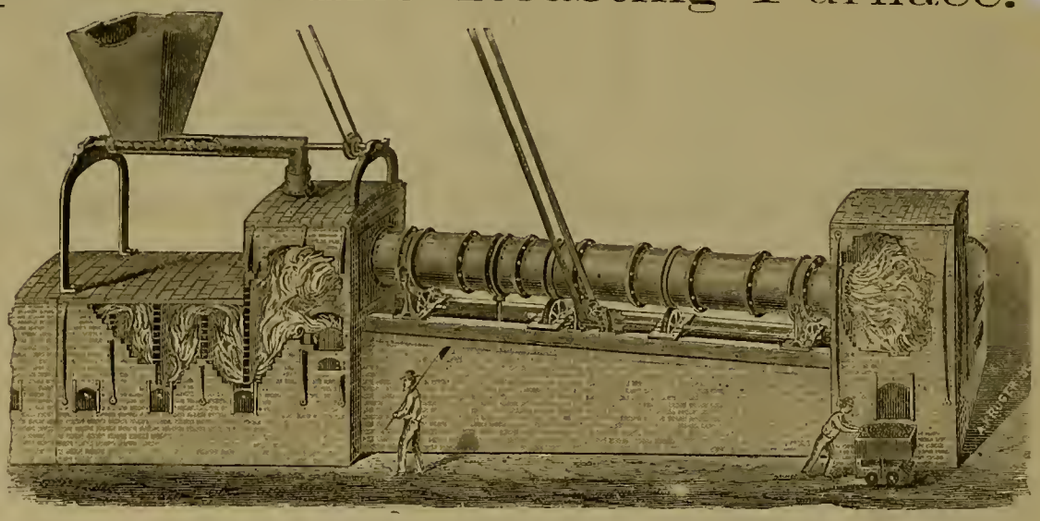
Howell's Improved White Roasting Furnace.



This cut represents the most improved construction of this unrivaled Furnace, the superiority of which over all others as regards cost and capacity, as well as the economical and thorough oxidization and chloridization of ore, is now generally conceded.

In this Furnace, as covered by the Howell and White patents, are combined the three acknowledged requisites for the thorough and economical roasting and chloridization of ores.

First.—Continuous progression through and discharge of the ores from the furnace—while in the meantime they are, by being constantly showered through the heated air and gases within it, exposed in the greatest possible degrees to their reducing action.

Second.—Subjecting the ores to this showering process any length of time that may be necessary, according to the character of the ore, for its thorough reduction. In passing through the furnace it ordinarily falls about 1,000 feet, all the time in direct contact with the flame.

Third.—Increasing the heat on the ores as they are progressed through the furnace.

In this respect this furnace excels all others, as none of them combine all these essential requisites. It will chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade

The first cost as well as the cost of operating it is less than that of any other furnace of equal capacity.

It requires no especial skill in management that cannot be readily acquired by any one capable of conducting an ordinary silver mill.

We manufacture various sizes adapted to a five, ten or twenty-stamp mill, and furnish plans by which any competent mill man can erect and operate it.

This furnace having the full or partial brick lined cylinder, embraces the devices covered by the patent to John Howell, as well as the original devices covered by the White patents, has been erected and operated successfully at the following mines in California, Nevada, Arizona and Montana: Camanche, Jefferson, Leopard, Utah, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry, Independence, Endowment and Alice. At least ten of them are now in active and successful operation, in some cases reducing ores of the most refractory character.

These facts are a sufficient attestation of the merits of this furnace.

The undersigned, with Mr. John Howell, are the sole owners of the Howell patent, and they have perfected arrangements with him, and also with Mr. J. M. Thompson, who is owner of an interest in the White patents, and as such is possessed of as full and perfect rights and powers under the same as the patentee himself, by which they have acquired the exclusive right to manufacture these furnaces for the Pacific States and Territories. We hereby *caution* all parties against purchasing the same from any others but ourselves, or the said Howell or Thompson, as we shall prosecute all parties infringing upon the same. STEINWAY

PIANOS TO EUROPE.

STEINWAY & SONS Orders From Europe

Have increased to an extent, necessitating the establishment of Warerooms in London, England, and connected with it is a Concert Hall, the whole combined making the most elegant Piano Warerooms in Europe, and stands there as a monument of American genius and industry.

It is impossible to mention in the limited space of an advertisement the innumerable triumphs of this energetic firm. They stand foremost as inventors in Piano building in America, and in that respect, no small compliment to their inventions is the undeniable endorsement of all their competitors, as shown in their imitative efforts. Certain principles of the Steinways, are, however, so completely protected, that no imitation or substitute is attempted at all, and the shallow method of crying such inventions down are resorted to and relied upon.

The Steinways designed and perfected the Overstrung and Iron Frame systems. The application of the Agraffe Arrangements to Square and Upright Pianos. The Patent Duplex Scale, creating the most beautiful treble tones, (the Duplex Scale is of recent invention and only to be found in Pianos sold recently). The improved Double Dampers. The later idea extending the Agraffes to every string in the Piano. The highest finish to all parts of the instrument, including first quality of ivory, ebony, felt, cloth, etc. The wood and varnish of such first-class character, that the employment of large capital and experience alone permits.

The name of Steinway has become a "household word" in American homes, and the satisfactory record of 18 years' trial on the Pacific Coast, in itself assures the purchaser that the investment is no speculation, but one of perfect security.

The oft-repeated story of rival makers claiming to have been Steinways' foreman, etc., should have no weight with purchasers. An immense manufacturing business like the Steinway's is divided into departments for the various classes of work, and a foreman of one department superintends that alone, and cannot be perfected in other details.

The Steinways (a numerous family) are the inventors and designors of the principles of their pianos, and are alone responsible for the thorough execution of their own ideas.

In the Machinery Department at the late Centennial Exhibition, Steinways were awarded a special medal for an invention for testing their iron frames under a pressure of 5,000 pounds to the square centimeter. (This award was distinct from their medal for the best pianos exhibited.) The iron frames in Steinway pianos are the only ones so tested, and while other makers rely on castings from an ordinary foundry, the Steinways maintain their own foundry, and manufacture a frame of *composite metal*, which adds greatly to the resonant qualities of the instrument in general.

It often occurs that the attempt is made to raise the character of pianos constructed on less costly principles to the rank that the Steinway maintains, by naming a price, the same, or nearly so. This method is frequently exposed by the perfect willingness of the dealer to make astonishing discounts for cash, or extremely long credits; systems not entertained in any first-class business. In selling a Steinway piano, a guarantee of worth is given protecting the purchaser for five years, and catalogues issued by the Pacific Coast Agencies have an uniform rate of prices in gold, and where desired a liberal installment plan is offered to responsible buyers, with an additional charge of simple interest on deferred payments. Catalogue mailed on application to

Steam Pumps.

Perhaps no field in the realm of practical mechanism has offered greater inducements to inventors' ingenuity than that of the mechanical manipulation, or otherwise, the pumping of water and other fluids. And why? One would laugh at a woodman endeavering to propel his saw log to the mill hy striking it on the end with some heavy device, consoling himself meanwhile with the thought that after each stroke it was so much nearer home.

Let us snbstitute water for the saw log and a piston operated hy some motive power for the striking device, and we arrive at the fundamental principle involved in a pump. Yet where is the analogy between the pump and the foregoing supposition concerning the saw log? If wo take a cylindrical tube, close one end, fill it with water, fit a piston in the other end, and then strike the piston with some heavy device such as a sledge hammer, the piston will not be forced into the cylinder an appreciable distance, thus showing the incomprehensihle nature of the water.

Here the analogy is forcibly seen, and it is this striking peculiarity that has rendered the perfection of steam machiuery necessarily retarded and surmounted with great difficulties.

It is ohvious therefore, that the raising or forcing of a continuous column of water at a uniform pressnre presents a problem the solution of which is by no means easy. Assuming that this can only he accomplished hy means of a piston traveling in a cylinder, the conditions governing its operations are such as to exclude from use many of the improved pumping appliances of to-day. It is evident that a constant flow and pressure cannot he attained where the crank movement is used in connection with the piston, for here we have a varying piston speed the irregularities of which cannot he compensated for by the expansihility of the air in the air chamber, neither can the air pressure fully overcome the pulsations that such motion would impart to the water. And as such construction necessitates the use of the fly wheel, a momentum would he attained which is not a little dangerous, considering the incompressible nature of the water.

A continnous pressure is approximated hy making the pump piston douhle acting, hut here the piston speed enters into the consideration, which speed can be uniform only in engines which do not use steam expansively. A quick reversing of stroke is essential toward the maintenance of a constant water pressure.

The valve mechanism is an important feature, as the prompt action of the valve is necessary, which cannot he obtained hy the use of the eccentric upon a revolving shaft.

That a pumping engine may successfully cope with all obstacles, it must fulfill the following conditions:

1. The reciprocating motion of the steam piston must he employed directly to pump water.

2. It must have a uniform piston speed (the duplex system is not here considered, for while it produces nearly absolute uniformity in water pressure, its additional expense must exclude it from use in ordinary mine pumps).

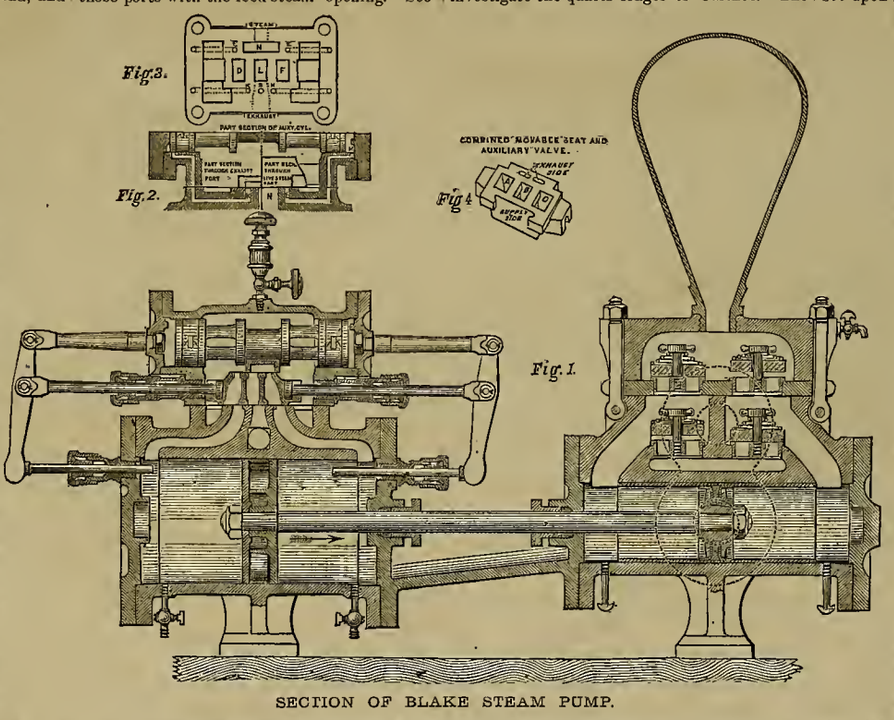
3. There must be no momentum, such as is obtained hy use of the fly wheel.

4. It must secure prompt valve action without the use of eccentric or cams.

5. It must combine cheapncss, durahility, compactness and accessihility for repairs with ability to compete in an economical sense with the hest pumping engiues.

The Blake pumping engine, of which we herewith present a section, may he considered the outgrowth of a close and careful study of the foregoing conditions. While here no labor has heen spared in making the steam end as near perfection as possihle, the improvement of the water end has not been neglected—an oversight too frequent in devices for pumping fluids. In the section the operating mechanism is clearly shown.

The mechanism of the steam end is simple and efficient. The steam valve, or rather valves, consists of a movahle seat and auxiliary valve actuated hy steam connections connected with links, which in turn are worked by means of tappet-rods passing into the cylinder through stuffing boxes in the cylinder heads, and are driven by direct contact with the alternate sides of the piston. The valve proper is of the ordinary *D* type and rides upon the auxiliary valve. It is operated by an auxiliary douhle piston moving in a cylindrical steam chest, which piston is operated by the alternate action of steam upon its opposite heads. Fig. 3 is a plan of the ports and valve seats in which *D* and *F* are the main inductiou or feed ports, and *L* the exhaust port. *E E* are the feed ports to the auxiliary piston. *N*, the port that connects those ports with the feed steam opening. Sec-



SECTION OF BLAKE STEAM PUMP.

tions of these ports are shown in Fig. 2, which gives a section of the secondary cylinder of steam chest. *K K* are the exhaust ports for the auxiliary piston, and *S* the opening to the main exhaust.

Fig. 4 is a perspective of the combined movahle seat and auxiliary valve in which the main ports, *A B C*, are shown, together with the steam and exhaust passages of the auxiliary steam chest. The three ports of the auxiliary valve are equal in area, and coincide in every position with the three ports of the main engine, thus virtually extending the engine ports. The mechanical connection between the movahle seat and the main piston is such that contact of the piston with the cylinder heads is impossihle, as the mechanism referred to gives positive lead, sufficient to allow the steam to cushion before the piston completes its stroke, therehy preventing "hammering," and likewise tending to overcome the pulsations that would otherwise he produced in the water, while it, at the same time, gives a quick reversal of stroke. Should the main piston at any time attain a velocity greater than that of the main valve piston, the auxiliary valve mechanism above referred to prevents the main piston from "running away," for here the auxiliary valve becomes what may be termed the main valve, and acts independently of the steam chest valve and piston,

The perfection of the pump proper has not heen neglected, as a glance at the cut will show. As there shown, it will he seen that both the feed and outlet valves are placed upon the upper side of the cylinder, thus offering great facility for inspection and repair, for, by simply removing the nuts from the clamp bolts, which are hinged at the bottom, the top cover of the water-chamher may be removed and access had to hoth sets of valves. The water valves are simple and durahle in construction and efficient in operation, though their construction is varied, as regards material and design, to suit the purpose intended. Freedom from complication of parts is one of the striking peculiarities of this pump.—*Polytechnic Review.*

The Quartz Ledges of Cariboo.

Eighteen months ago the Elliott ministry, then controlling a majority of the Parliament in British Columhia, employed Mr. Harper to investigate the quartz ledges of Carihoo. The step was a very popular one. Cariboo bas heen extraordinarily rich in its placer mines. Many very euergetic, intelligent and good people from Canada and the world at large, found themselves in possession of properties in those hyperhorean mountains, while the outgoing stages were pretty well filled the season through, the incoming stages were frequently empty. There was danger of Carihoo in particular, and the British Colnmhian interior generally, with Victoria as its point of supply, being left high and dry, if no other mines should he discovered that would justify the attention of the miuers and of capitalists.

Elliott's actiou was wise, and as commendahle as it was popular. The politicians and the newspapers of Victoria have, unfortunately, very little respect for their constituencies, and it is impossible to tell at present, whether the Carihoo quartz action was not purely a "political dodge," intended to confound the wily Walkem.

Mr. Harper found numerous ores of astonishing richness where the good people of Carihoo had been able to find previously only modest results. They have had a government assayer at Barkerville for 15 years, and the fact that these ores were remarkahly rich had escaped his crucihles. It was a well-known fact, however, that very little thoroughness had heen directed to quartz. There was a common lack of faith in the regularity, and in the practically necessary concentration of the ore deposits, to justify mining and milling; at the same time that there were not lacking scores of more or less enthusiastic believers in quartz. "Where did all this gold come from?" was the question they wanted to have answered. Harper's reports settled the matter, and the Victoria merchants were deligthed to see the Victoria papers fulfilling their proper function in fostering another gold excitement.

Little Walkam now turns the table on Elliott; and there are people in Victoria so inconsiderate as to say that the late Premier and his "popular mining engineer" overdid the Cariboo quartz.

Among other experts from this city who have gone to investigate Cariboo, are J. S. Phillips and E. N. Riotte, men whose capabilities and character are widely known. Neither of them belong to that class of "popular mining engineers" who are sought by miuing capitalists when they have occasion to make use of a report to their liking. We congratulate Cariboo upon having drawn to itself, through Mr. Elliott's efforts—whether politically honest or otherwise—the attention that country merits in view of its placer yield.

"The recent scare," says an observer in the Victoria *Colonist*, of June 26th, "in relation to mining matters, which, like a thunderclap, hurst over our devoted heads, has destroyed the feeling of confidence in the success of our present plans and hopes. It may be that we cannot bring ourselves to helieve the truth when brought home to us with such sudden and alarming force. It may he that we are so firmly wedded to what are our firm convictions, hased as they were, on undisputed authority of the richness and permanency of the Bonanza lode, were too hasty in placing such implicit faith. such unbounded confidence, and absolute trust in men whose character and capabilities we knew little or nothing of; whose reports and statements were swallowed with avidity. It is nevertheless patent (continues the observer) that there has been a deep-rooted scheme, dishonorahle in its secrecy and unlawful in its willful misrepresentations, to destroy the faith of the Victorians and of the Victoria stock hoard in Cariboo quartz. And the principal actor in this plot would seem to be Mr. Riotte."

From which it appears, on reading a little further, that Mr. Riotte has had the malignancy to pronounce a certain ledge he has examined worthless. The "Observer" politely concludes by "suggesting to Mr. Riotte, now that his carcer of usefulncss is ended in British Columbia," and that he "retire from the (pleasant) arena and hetake himself to fresh woods and pastures new." Our eye falls—in a corner of the same paper—on a three-line item to the effect that Mr. Harper "has severed his connection with private mining companies at Carihoo."

It is to he presumed that Mr. Riotte will learn the lesson, after this, to make his reports on miues a little more popular.

BULLION SHIPMENTS.—Since our last issue shipments of hullion from the promiuent mines have been as follows: Christy, June 30th, $4,175; Tyho Con., June 28th, $8,023 34; Northern Belle, June 29th, $5,764.40; California, July 2d, $160,921.45; Standard, July 2d, $20,328.66; Northern Belle, July 1st, $5,849.70; Modoc, June 30th, $3,777.06; Con. Virginia, July 2d, $148,653.74; Gila, June 30th, $4,647; McCracken, July 5th, $14,023 33; Modoc, July 4th, $3,850.57; Northern Belle, July 3d, $5,967.58; De Frees, July 8th, $10,000; Alexander, July 6th, $10,800.39; Hillside, July 3d, $8,268; Tyho Con., June 30th, $8,419.37; Northern Belle, July 6th, $7,087.67; Tybo Con., July 3d, $8,616.88; Christy, July 8th, $5,340; Independence, July 8th, $10,000; Standard, July 7th, $43,377.67.

THERE are over 80,000 children in San Francisco under the age of 18.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds

The San Juan Mines.

EDITORS PRESS;—As a constant reader of your valuable paper, I notice the absence of general mining news from Colorado, and especially from the San Juan country. We are young in years, but the richness of our mines has attracted the capitalists of the East, and as we are on the Pacific slope of the Rocky mountains, we may claim some notice in the West.

The center of this mining camp is Silverton, a town four years old, with about 3,000 inhabitants, and located in one of the most beautiful parks in the Rocky mountains. The best mines are located from one to 12 miles around this place. We have sulphuret ores, heavy spar and gray copper, ruby silver and galena ores. A number of mines have paid their way from the grass roots, and this speaks volumes for their richness, when we only get 41 cents per ounce for 100-ounce ore, and 62 cents per ounce for 200-ounce ore. Ore has to be packed on burros, and freight is high yet. From this can be seen that ore less than 100 ounces would not pay unless easily extracted and in great quantity. Still there are a great many mines remunerative to their owners. The pioneer and only smelting firm of San Juan county, at present, is Geo. Greene & Co., at Silverton. They have treated ores successfully for the last two years and are increasing their capacity to 30 tons a day. The present prosperity of the camp is largely due to them, and although they don't pay such prices for ore as the miner could wish, they have helped them along to open their mines. The Aspen and Victory, on Hazelton mountain, are furnishing most of the ore (galena) to these works.

The lixiviation works of Messrs. Dow & Waters, at Gladstone, on Cement creek, will be ready for operation in a few weeks. There are a number of mines within four miles, on Cement creek and Poughkeepsie gulch, which have a good many tons of ore on the dump which is adapted to the process of lixiviation. Messrs. Dow & Waters are working the Pride of the Alps and Poughkeepsie lodes under lease, and are extracting a large quantity of ore. These are two of the most prominent veins of this district. The Columbia and Helvetia have been extensively worked, a good many tons of ore are on the dump and plenty is in sight in the stopes. The Saxon and Alaska will yield some rich ore this summer, and there is a half a dozen more. All these mines are owned by individuals. They have done a good deal of work on their property, and had no other resources than what they took out of their mines. If companies would own some of this property and open it extensively, large dividends could be declared monthly.

Crook Bros., of New York, will build a smelter at Boulder gulch, one mile from Silverton. Their reputation for treating ores is so well known it needs no comment. Their addition to this camp will open a new epoch to the prosperity of the miners who have leads with low-grade ore. Other capitalists are bound to follow such enterprises, and the day is not far distant when San Juan county will be known as the best mining camp in Colorado.

F. STEINEGER.

Silverton, Col., June, 1878.

Salt River, Arizona.

[Correspondence of the PRESS.]

Irrigating with Saline Water.

EDITORS PRESS:—Here I am, "up Salt River." Please, Messrs. Editors, take this in a geographical and not in a political sense. Still the situation is a trying one, for this is about as rough and worthless a country as lies out of doors. This river is laid down on the earlier maps as the Saliuas, and I cannot help thinking it would have been well to have retained that more euphoneous and equally appropriate name. The stream derives its name from the saline character of its waters, which are so strongly impregnated with salt that it requires some time for new comers to accustom themselves to its use. It is the largest and most important of all the interior streams of Arizona. On its banks are the productive farming lands of Phenix and Tempe, where the happy ranchers live without anxiety about the failure of crops, for they know to a certainty that every acre properly tilled will yield them from 30 to 60 bushels of grain every year, and that their lands are not being impoverished or exhausted so rapidly as those cultivated without irrigation.

Though some have had the hardihood to claim that this salt is a benefit to the land, no well informed person will be likely to admit it. Salt in great quantities has never been recognized as a fertilizer and salt marshes have always been found difficult to reclaim for agricultural purposes, and there is no question but the purification of the water of the salt it contains, were this practicable, would be of great advantage to the settlers along this river. It may even transpire in the future that the constant use of this water will have such an injurious effect upon the soil as to eventually render it worthless.

Where the Salt Comes From.

The water of this river is not salty at its source, but acquires this property from several springs near its banks and along its tributaries, far up in the Apache mountains. The principal and most important of these springs is located directly on its northwest side, about 30 miles below its junction with White river, and the same distance in a direct line from Globe City. This spring, or rather group of springs, runs a head of about six miners' inches of water, carrying five grains of salt to the ounce. An analysis of some stalactites taken from the overhanging rocks resulted in 86% chloride of sodium, the remaining 14% consisting of impurities common to the mineral.

Turning this Salt to Good Account.

The utilization of so large a supply of this commodity is a want that cannot be long postponed, because of the rapidly growing demand for it in Globe and neighboring mining districts for the reduction of refractory ores. In fact, an enterprise looking to that end would be a paying one to parties able to furnish the necessary capital. The evaporation could be carried on with the aid of the sun alone, whose heat, reflected from the high cliffs on either side of the river, heats down with great intensity.

Basaltic Mesas.

The reason that these springs have not yet been so utilized nor even appropriated by the greedy speculator is that they lie in a region almost inaccessible because of its steep cliffs and deep canyons. Only the roving Indian scout and the hardiest of prospectors have ever visited it, though so near to Globe, and nearer still to McMillenville, the site of the famous Stonewall mine. Towards its sources, Salt river and its tributaries run through "box canyons," being deep cuts with perpendicular walls on either side, formed in the basaltic rock by the constant wear of the streams. The ruggedness of the country here is due to the peculiarities of this rock, which are great hardness, horizontal stratification and right-angled fracture. Thus the result of denudation is always a cliff and never a slope, as in countries composed of friable rock or that having more tendency to decomposition. The hardy prospector, picking his way among the loose rocks of the "mesas" or high plains, often finds himself trembling on the verge of one of these fearful precipices, many hundred feet above the river, which winds, like a silver wire, through the canyons below, and often it is a day's labor or more to hunt out some by canyon or old Apache trail by which to effect a descent to the water below. To make one's way with expedition or even with safety among these canyons, requires an intimate acquaintance with their devious windings as well as with the Indian trails, which latter have often, in times past, been the safe lurking places of the wily savage. The country has not yet been explored for a wagon route from Globe to the Springs, nor will it be easy to find a feasible route for this purpose, though a mule trail could be easily and cheaply constructed. Packing would, however, be expensive, besides being objectionable on other accounts. It may be found practicable at certain seasons of the year to raft the salt down the river, some 20 miles, to the crossing of the Globe and Pheuix road, at a point about 40 miles from the former. In any event, these springs are bound to become of great value, as there is no prospect that salt can ever be supplied at Globe and surrounding mining camps from any other point for less than $70 per ton, it being, of course, much higher at present.

Picacho Colorado, Arizona, June 8th, 1878.

THE WAY THEY TELL IT.—A correspondent of an Eastern paper relates the story of James G. Fair this wise: There is a man alive at this present moment who, if he were so minded, could give his daughter a marriage portion of one hundred and fifty million dollars. He would then have about fifty millions left for himself. He lives half-way up a mountain-side in Nevada, and his daughter lives with him. Seven years ago he was a poor man; to-day he is the silver king of America. He has dug two hundred million dollars' worth of silver out of the hill he is living on, and has about two hundred millions more yet to dig. If he lives three years longer he will be the richest man in the world. His name is James Fair, and he is the manager, superintendent, chief partner, and principal shareholder in the Consolidated Virginia and California silver mines, known to men as the "big bonanzas." He has an army of men toiling for him day and night, down in the very depths of the earth, digging, picking, blasting and crushing a thousand tons of rock every twenty-four hours. He works as hard as any man of them. The man, who, by his own unaided exertions, can rise to such marvelous wealth in so short a time is worth knowing something about. It is worth while to hear how such a fabulous fortune can be accumulated.

LIVELY BUT ROUGH.—Sheriff Harper returned this morning from a trip to Ione, Grantsville and that portion of Nye county. He says Grantsville is lively, but the roughest camp this side of the Union Pacific railroad; that it is crowded with tramps, roughs, scrub fighters, thieves and scalawags, who make day disorderly and night hideous. He thinks the place will pan out a big ledge of criminal business for the Nye county courts.—*Reese River Reveille.*

Union Mining District.

A correspondent at the new camp sends us the following particulars about the new district: The district recently organized embraces an extensive mining section, heretofore comparatively unknown. It is situated sixty miles from Eureka, and about seven miles from the E. & P. R. R., by way of Bruffy's Hot Springs. There are immense tracts of timber throughout the district and adjoining country, with water enough to run an unlimited number of furnaces. The great mineral belt of the district trends nearly north and south, and can be easily traced for nearly six miles. On the north end of this belt are immense bodies of the finest and easiest smelted ores in the country, working from fifty to one hundred and fifty dollars per ton in silver, and from twenty to sixty per cent. in lead. At the south end the ore changes materially—resembling the rich chloride rock found at Mineral Hill, assays of which range all the way from seventy-five to two hundred and fifty dollars per ton. About one mile east of this, another ledge crops out for a distance of a mile or more, bearing rich carbonates similar to the ores of Ruby Hill, the average assays of which are about fifty dollars in silver and twenty-five dollars in gold. Further east are other well-defined ledges, easily traced for several miles in length; some assays of rock brought in from this locality went as high as $3,000 to the ton. The district embraces an unlimited number of spurs and cross veins, which would require too much space to describe at present. Suffice it to say that the little camp has a bright future, and if we may judge by the present outlook, is destined at no distant day to take rank as a bullion producer of the first magnitude.—*Eureka Sentinel.*

BRIEF HISTORY OF THE SUTRO TUNNEL ENTERPRISE.—Ground was broken for the Sutro tunnel on the 19th of October, 1869. The work has therefore required eight years, eight months and ten days to complete. The progress was very slow at first, all drilling having been by hand; but in the spring of 1874, experiments with a Burleigh drill having demonstrated the advantages to be derived from the use of that machine, a carriage capable of supporting six of those drills while at work was made, and on the 22d of June, 1874, four were started. The progress was now much more rapid than ever before in the history of tunneling in the world, and on August 7th, in the same year, two more drills were put to work. This made six altogether. From that date the average progress was over 300 feet per month up to April, 1877, when the header having entered the broad Comstock mineral belt, the heat became so intense that two drills had to be taken off the carriage. From that day the average monthly progress did not exceed 250 feet. Work has been continued uninterruptedly from the time that ground was broken until to-day, but at times only two men were at work in the tunnel. The greatest progress was in December, 1875, when the header was advanced 417 feet, and the least in October, 1870, when it was only advanced 19 feet. The total length of the tunnel, as stated in the official chart published last September, is 20,170 feet. The tunnel being connected with the Comstock workings, the next move of Mr. Sutro will doubtless be to start north and south drifts to connect with all the mines on the lode. The work has cost nearly $4,000,000.—*Virginia Chronicle.*

PHENIX MINE, AMADOR COUNTY.—The Ione City *News* thus describes a visit to the Pheuix mine: In this mine there are two shafts, the north shaft being 1,200 feet deep and 18 feet wide at the bottom. The north drift in this shaft, according to the opinions of those who "savy," promise everything desirable in the way of rich treasures. The south shaft is 1,100 feet deep, and 35 feet wide at the bottom. From this level we were shown handsome specimens of free gold bearing ore exceedingly rich. The level is now in 150 feet running south. The 1000 level in the same shaft is about 46 feet wide, presenting a strong body of ore of the full width and almost entirely without a seam. The level is now 800 feet from the south shaft and the ore is being taken out in a solid body, with indications of widening as the level is extended. All this rock carries a large percentage of sulphurets, of which the mine produces three tons daily. The highest assay value is $175; the second, $150. The sulphurets are reduced by the Phenix Sulphurets works, situated at Drytown, the works guaranteeing 85% of the assay value. The average yield per month, including sulphurets, is from $25,000 to $40,000, and prospects suggest that this handsome sum will be augmented. Alvinza Hayward, the San Francisco capitalist, is the chief, if not the sole, owner of this snug piece of property.

WOOD FROM ALPINE COUNTY.—The big drive of 50,000 cords of wood is now on its way down the Carson river to Empire City. The head of the drive is expected to arrive in a day or two. The parties who are bringing down the drive are to receive $25,000 or 50 cents per cord for the job. They take the wood at the head of the Carson river and are to land it at the Mexican dam. The river is now falling a little, and unless there shall come a very warm spell or a rain at the critical time, the contractors are likely to have some trouble in bringing in the tail end of the drive. To take the wood out of the river will give employment to a considerable number of men for some time.—*Carson Tribune.*

Transparent Pictures on Glass—Chromatropes.

The names of chromatropes is given to certain revolving multi-colored rosettes which, when projected by magic lanterns, produce the effect of balloons and throw out lozenges, spheres and brilliant stars in every direction. It is one of the most beautiful examples of the continuance of luminous rays on the retina. They are obtained by making two glasses which have similar designs turn in contrary directions by means of a wheel work. The opening in which the two frames revolve is cut in a strip of wood. They can be made in the following manner:

Some squares of very white glass are cut in circular form over a paper model, and the edges smoothed on a grindstone. The design is first traced on a paper securely fastened, but not too thick. The drawing is generally formed of numerous narrow oblique stripes, which, crossing one another when the glasses are turned in opposite directions, produce regular figures. The drawing must be made a little smaller than the glass, so as to make allowance for the frame. The paper is cut of the exact size of the glass. The glass, which must be well polished, is put over the drawing and the latter is then copied on with a pen and ink or black varnish. The reproduction is more easily obtained by the following process: By attaching sketching paper with strips of gummed paper under and over the glass. The sketching paper must have a coating of black or blue on the side next the glass. The drawing is on the top. The three folds being of the same size and perfectly coinciding, on going over the drawing with a fine drawing-point the design will be reproduced on the glass.

As two glasses are required, the process has to be repeated. If there are portions of the glass large enough to be paneled black, this can be done with black bituminous varnish, but it more convenient to paste on black paper which is cut by having a tracing of the design, or by making use of red or blue tracing paper, so as to show the outlines. This paper is doubled and the edges glued and then cut with scissors or a good pointer on glass or zinc. A little copal varnish will keep them on the glass. The transparent colors are then applied to each glass. The finest stripes are in the center and the color is put on with a steel pen. The light colors are put on first. The colors on one glass must not be different from those on the other, nor must they neutralize each other when superposed. Care must therefore be taken not to place yellow and violet opposite to one another, nor green and red, nor orange and blue, as these colors would negative each other and only give grayish tints. The effects of running water, of flames or smoke rising in the air, are obtained by projecting on the drawing a chromatrope which revolves in a second projecting apparatus placed alongside the first. The chromatrope must have green stripes to imitate water, orange for fire and fuliginous or sooty rays to imitate smoke. These lines cross on the corresponding space of the drawing which is alongside, and which is projected on the screen. Snow effects are obtained with black paper, perforated with small holes and rolled up and down in the second projector. The summer landscape is first seen; the second apparatus is seen progressively, in which the perforated paper is rolled up so that the snow seems to fall on the screen, and finally the view of summer on the first apparatus is replaced by the winter scene. Other pictures with mechanical effects can be had, which represent mills with the wheels in motion, beehives with the insects flying round them, ships in motion, stars revolving in their orbits, etc. The moving objects of thaumatrope and the symmetrical and infinite variety of the kalcidescope can be projected on the screen.—*Translated from the French for the Jeweler.*

MATTERS ABOUT TUSCARORA.—We have heard that a rich silver-bearing quartz ledge has been discovered in the Revenue mine in this district. The new find is remarkably fertile in chloride ore, which assays an average of $600 per ton. The ledge is said to be seven feet in thickness, and is probably one of the richest discoveries yet made in northern Nevada. We have the promise of more light upon the new bonanza shortly. Lone mountain is a solitary butte of lofty proportions, which rises midway between Tuscarora and Elko. It is one of the most conspicuous landmarks in the State, as it is visible from every point of the compass at the distance of 50 miles or more from its summit. Lone mountain contains several strong ledges and deposits of copper, lead and iron.—*Times-Review.*

INDIAN RESERVATION IN MONTANA.—Frank Decker, Agency miller, says that at no time during the past eight years, in which he has had knowledge of agency affairs, have the Indians made such remarkable progress in the arts of civilization as during the past year. He has ground about 8,000 bushels of grain at the agency mill during the last season, and he knows of there being made by Indians over 40,000 rails, which now inclose ground that is under cultivation, in addition to former farms. —*Independent.*

THE Valparaiso *Mercury* reports an immensely rich silver-bearing district to have been discovered in the vicinity of the Rio Colorado, in the Andes range of mountains and not very far from the city of Santiago. Assays of the ores are said to average $8,000 per ton.

MECHANICAL PROGRESS.

The Application of the Microphone.

We lately gave a brief description of the microphone, which in addition to the transmission of sound as in the telephone magnifies it or rather increases its volume immeasely. We read in *Iron* that one of the earliest practical applications of the microphone has been made in England, by Sir Henry Thompsen, who, recently lectured at University College Hospital on the use of the microphone in the diagnosis of stone in the bladder. The lecturer explained the principle of the microphone, and showed how a small accoustic wave is converted by it into a large electrical vibration which is reconverted into sound at the diaphragm of the telephone, where it is received by the ear of the operator. The minute wave transmitted through the sound on its impact with a very small stone is thus so magnified that the operator is enabled to determine with certainty on the presence of the smallest stone or particle of stone or other foreign substance. The experiments were conducted with a couple of steel sounds, each fitted with the microphone, and an artificial bladder, in which was concealed, in turbid fluid, a naturally-formed uric-acid stone, about as large as a pea. In concluding his lecture, Sir Henry stated that the honor of this application of the microphone to surgery had been won by London from the great Continental centers of surgical science.

We are are also furnished with the latest authentic information concerning the construction of the microphone by Dr. Mann, as follows: "By the microphone sounds are heard which are more faint than those with which the stethoscope deals in explorations of sounds within the chest. There is, therefore, reason for the hope that with some further development of the powers of an instrument new but in its early infancy, we may yet find that it will prove of great service by hereafter detecting sounds in the living economy which are not now distinguishable by the ear. My own ground for this belief is a confidence that some intermediate instrumental agency will be devised which will be capable of transmitting such soft-sound vibrations as originate in the movements of the living economy to the charcoal of the microphone, and so bring them within the sphere of its operations. The soft shock of the contractions of the heart must, so to speak, have some kind of sounding board of their own before they can be efficiently taken up for augmentation by the carbon of the microphone. That, I think, is the intermediate agency which the ingenuity of science has now to endeavor to supply. I may also be permitted to say that the microphone is essentially a rod of charcoal resting, by the light contact of its own weight, upon a disc of charcoal. The perfection of that contact for the transmission of the electrical current varies with the condition of sonorous vibration which is present in the carbon mass at each instant.

MECHANICAL EQUIVALENT TO HEAT.—According to *Cotton*, Prof. H. F. Webber has calculated the mechanical value of the unit of heat from the results of experiments based on the consideration that in a galvanic circuit, traversed by a constant current, in which evolution of heat is the only action of the flow of electricity, the amount of heat developed is the equivalent of the work expended at the same time. Both weak currents circulating for a long time and strong currents circulating for a short time were employed. The mean obtained from a large number of experiments was 428.15 meter-kilogrammes, temperature being measured on the air thermometer. From the relation between the specific heats of atmospheric air the mechanical equivalent is found to be 428.95. In 1849, from friction experiments, Joule found the value 424.39, and his more recent experiments confirm this result. Unfortunately, this number cannot be compared with that obtained from the specific heats of air (428.95), since the units of reference are different. An air thermometer was employed in the latter case, whereas Joule's unit of temperature is that of his mercury thermometer. These two temperature units may possibly differ by 1%.

CAR WHEELS.—The master car builder of the Michigan Central road tells the *Railway Age* that the new 42-inch wheels introduced on the passenger coaches, last summer, are proving to be of great merit and durability. The average 33-inch car wheel is considered to have done good service when it has been run 50,000 miles. The 42 inch wheels on the Michigan Central have run 80,000 miles, and Mr. Miller is confident that a run of 100,000 miles will not affect them to the extent that half that distance does the smaller sized wheels.

SAVING LIFE AT SEA.—The Council of the Society of Arts offers its gold medal for the best means of saving life at sea, when a vessel has to be abandoned suddenly, say with only five minutes' warning; the shore or other vessels being in sight. Appliances intended for the competition must be sent in not later than the 31st of October, 1878, addressed to the Secretary, Society of Arts, John Street, Adelphi, London, W. C., and must in every case be accompanied by a short description.

SUCTION BY ELASTIC TUBES.—Some improvements in the construction of hydraulic and air pumps, in which the sucking and forcing action is derived from the alternate compression and expansion of elastic tubes, have been invented by Mr. Francois Bruyas, of Paris. The pump consists of a body or framework, which may be formed of one or more sections of a metal pipe of any required caliber. Within this there is a double cross piece, in the center of which is mounted the driving shaft, carrying an adjustable arm, terminated by bearings of the revolving runner. A tube of caoutchouc or other suitable elastic and compressible material, of any required caliber, is coiled inside the frame, from which its extremities egress in opposite directions through openings. A handle is keyed to the end of the shaft and may be replaced by a fly-wheel or other equivalent. In the rotation of the shaft, the runner in its passage round the circular body compresses the tube against the plane surface of the latter, thus giving rise to suction through the end of the pipe immersed in the fluid and to forcing through the upper or outlet extremity. The form, dimensions and general details of this apparatus may be varied according to circumstances.

THE USE OF ANTIMONY IN GALVANISM.—Mr. R. J. Nunn, writing to the *Journal* of the Society of Arts on this subject, asks to be allowed to call the attention of electricians to the use of antimony as a negative element to replace carbon in some galvanic batteries, those, for example, in which sulphuric acid is employed, as an exciting fluid. He says, I have used this metal for this purpose for about five years in some batteries, employed for medical purposes, and the result has been satisfactory. The advantages are—its cheapness; the absence of scaling or disintegration, while the broken plates always retain their commercial value, and may be melted up and recast; finally, galvanization begins immediately upon immersion, which is often not the case with carbon. The chief disadvantage of antimony is its brittleness when formed into thin plates, but this I have corrected by casting it on a core of toughor metal, such as copper, or by alloying it with a very small percentage of some other metal. Although, perhaps, not so good a negative as carbon, the superior conductivity and other advantages of antimony may often make it a useful galvanic element.

A DINING ROOM CLOCK.—There was recently received at the Milan exposition a great curiosity in the shape of a clock made entirely of bread. The maker is a Peruvian, a native Indian, and he has devoted three years of his life to the construction of this curiosity. He was very poor, and being without means to purchase the necessary metal deprived himself regularly of a portion of his daily bread, which he devoted to the construction of this curiosity, eating the crust and saving the soft part for his work. He made use of a certain salt to solidify his material, and when the various pieces were dry they were perfectly hard and insoluble in water. The clock is of respectable size, and goes perfectly well. The case, which is also of hardened bread, displays great talent, both in design and execution, and taken altogether it would be difficult to find a greater curiosity.

JAPANESE COPPER CASTINGS.—Before the Iron and Steel Institute, at its recent London meeting, Dr. Percy gave some particulars as to the manufacture of Japanese copper. Bars of this metal present a beautiful rose-colored tint on their surface, which is due to an extremely thin and pertinaciously adherent film of red oxide of copper or cuprous oxide. This tint is not in the least degree affected by free exposure to the atmosphere. Dr. Percy placed before the meeting bars which had been in his possession for 30 years, and which had undergone no change, although freely exposed to the atmosphere. The secret of this result lies in casting the copper under water, the metal being very highly heated and the water being also made hot. Dr. Percy stated that he had succeeded in casting copper in this way, and had produced similar results to those shown in the Japanese metal.

BISMUTH PLATING.—Copper or brass may be plated with bismuth in a bath composed of 25 or 30 grammes of ammoniacal chloride of bismuth per liter of water slightly acidulated with hydrochloric acid, operated cold. If heated to 100° the bismuth will not deposit. A single Bunsen cell only is necessary; with a single Daniell cell the deposit is long forming, and but slight. On coming from the bath the articles are covered with a dark deposit, under which is the bismuth with its especial brilliancy, and adhering strongly. By substituting the double chloride of antimony and ammonium antimony may be similarly deposited.

THE DIRECT CABLE DUPLEXED.—Dr. Muirhead has just successfully applied the duplex system to the direct cable between Torbay and Ireland, the longest line yet duplexed. Trial tests show an actual speed in working commercial messages of from 17 to 20 words a minute, thereby doubling the capacity of the cable.

NEW WHEEL TIRE.—A new wheel tire has recently been invented. It consists in passing around the usual tire a rubber tire, and around this again an iron tire made in sections, so that each section may yield inward as the weight comes upon it. It is said to lessen noise, jarring and wear.

SCIENTIFIC PROGRESS.

Compounds of Sulphur and Bromine.

Mr. J. B. Hannay recently presented a paper at a meeting of the London Chemical Society "On the Action of Bromine upon Sulphur." On treating ordinary flowers of sulphur with bromine, the author found that some of the sulphur remains undissolved. This insoluble residue was found to consist entirely of prismatic sulphur, and amounted to 0.08% of the sulphur used. Carbon disulphide leaves about 0.12% undissolved. Roll sulphur when treated with bromine dissolves completely. The author examined with a spectroscope the vapor overlying a mixture containing SBr. He found that even at 0° the vapor gave the characteristic spectrum of bromine vapor as mapped by Roscoe and Thorpe. If more sulphur were dissolved, however, the spectrum disappeared; thus, with a layer of liquid 0.5 meter thick, the absorption spectrum ceased to be visible in a liquid containing S^3 Br at + 42°, S^5 Br^2 + 33°, S^2 B^2 + 25°, S^4 Br^3 + 13°, SBr + 3°. The author finds that the liquid in large mass begins to boil at 72°, and rises without any pause, so that no evidence of the existence of a definite compound can be obtained by the boiling points. On mixing bromine and sulphur in the requisite amount, a rise of temperature of 20° was observed; some of this rise the author believes to be due to the change of state of the sulphur, because the amount of heat when plastic sulphur is used is distinctly less, only 12°. The author also estimated the specific gravity of various compounds or mixtures S^3 Br 2.293, S^2 Br 2.625, SBr 2.628, SBr^2 2.820, SBr^3 2.880, SBr^4 2.905, but without obtaining any evidence of the existence of SB^2. An examination of the freezing points showed that the liquids became oily without solidifying, even at temperatures at which bromine is solid. The estimation of the vapor tension was also without avail. If a small quantity of arseuic be dissolved in the liquid, SBr, and the mixture cooled to 18°, beautiful dark-red crystals are obtained of the composition AsS^2 Br^3, probably AsSBr, SBr^2. The author therefore concludes that the action of any quantity of bromine on any quantity of sulphur is an action on the whole mass and not in multiple proportion, but that if at low temperatures the compound SBr^2 meets a body with which it can form a molecular combination it assumes the crystalline form in conjunction with such a body. The action of bromine upon sulphur increases in a regular manner up to SBr^2, totally ignoring SBr; above SBr^2 we may have another curve to SBr^4 and another fainter curve to SBr^8 but we have no evidence of the existence of S^2 Br^2.

High Melting and Boiling Points.

At the late meeting of the English Chemical Society there was a paper "On the Determination of High Boiling Points," by T. Carnelly and W. C. Williams. The determination of the melting points of a large number of metallic salts by Carnelly enabled the authors, in cases where only approximate results were required, to ascertain the boiling point of a substance by observing whether or not certain salts fuse when exposed to the vapor of the substance in question when boiling. The metallic salts are contained in capillary tubes thus determined:—S boils 446°-451°; Regnault gives 447°. Anthracene 339°-359°; HgI_2 339°-359°; AsI_3 394°-414°; $BiCl_3$ 427°-439°; SbI_3 414°-427°; $ZnBr_2$ 695°-699°; $ZnCl_2$ 708°-719°; PlCl, 719°-731°; NI, 806°-814°; Cd, 772°.

Another paper treated of High Melting Points, by T. Carnelly. The author has carefully investigated and got rid of two sources of error which existed previously in his method. He now uses a much finer platinum wire to suspend the crucible, and has redetermined the value of his colorimiter with very great care. In the present paper he gives the melting points of over 100 substances and promises in a short time some interesting theoretical results which he has deduced from the above observations. The most important being that in simple binary compounds one of the elements remains the same when the melting point is a periodic function of the atomic weight of the other. The author also hopes to be able to indicate a method by which many unknown melting points may be predicted.

NEW TEST FOR GLYCERINE.—A paper was recently read before the London Chemical Society "On a New Test for Glycerine," by A. Senier, M. D., and A. J. G. Lowe. This test is founded on the fact observed by Iles, that borax, when treated with glycerine, gives to a Bunsen flame the green color characteristic of boracic acid. The test is applied by the authors thus: The solution is rendered slightly alkaline by dilute soda and a borax bead placed in it for a short time. The bead is then held in a Bunsen flame, if the solution contains one per cent of glycerine a distinct reaction is observed; erythrite and glycol give the same color, or a little of the solution is mixed with some powdered borax, and some of the mixture placed on a platinum loop and treated as before. By means of this test, after concentration, etc., 1-10th of a per cent. of glycerine was detected in beer, one per cent. in sherry, one per cent. in milk, five per cent. in treacle.

Helminthology.

Important additions have been made to this science during the past year, says the *Medical Record*, and the necessity for more extended investigations is evident. A recent discovery in helminthology has important relation to the origin of many obscure diseases. It appears that a Mr. Bancroft wrote from Brisbane, in April, 1877, and incidentally remarked: "I wonder if mosquitoes could suck up the hematozoa and convey them to water! They appear to die in water. I will examine some mosquitoes that have bitten a patient, to see if they suck up the 'filariæ.'" At the time Bancroft was surmising, Dr. Manson, of India, demonstrated this to be a fact. In November, 1877, Dr. Manson wrote to Dr. Spencer Cobbold, the eminent helminthelegist, announcing the discovery of this parasite in the stomachs of the mosquitoes, which had fed on hæmatozoal patients, describing also the developmental changes it undergoes during its residence in the insect.

He also supplements the 15 cases of this human hæmatozoa, giving details of no less than 35 additional cases, and a mass of valuable statistics in relation to the prevalence of "*Filaria sanguinis hominis*," Thus, what the Russian traveler Tedscheuko showed in relation to the case of the "cycleps," considered as the host of the Guinea worm, Manson has shown to obtain in the case of the "Culex mosquito." True, there was a difference in detail, but both play the role of intermediate bearer, the little crustacean and the small mosquito. Dr. Cobbold, as a practical comment on these discoveries, well remarks that "if physicians will only reflect to what extent diseases hitherto obscure are to be associated with the bite of a gnat, they will, perhaps, be not less ready than hitherto to extend a helping hand to those who, at great sacrifice, labor in the fields of helminthology."

A New Infusorian.

Under the name of *Leptodiscus medusoides* Hertwig describes an exceedingly interesting noctiluca-like organism, which he had the good fortune to discover in the harbor of Messina, during the winter of 1876-77. The New York *Independent* says this new form is perfectly discoid in shape, with the flagellum characteristic of noctilucæ. Its size varies, measured across the disc, from 0.6 min. to 1.5 min. The disc is thickest in the center; somewhat raised or convex on the dorsal side, while the ventral is concave. Near the ventral surface and in the center there is a bipartite, oroid nucleus, the smaller half of which is homogeneous, the larger granular. The numerous oil globules are imbedded just beneath the dorsal integument; but, with the exception of the whitish spot (granular area) in the center of the disc, is clear and transparent, exhibiting slight iridescence of the convex side. As the name indicates, this organism is Medusa-like; but this likeness becomes still more strikingly manifest when the organism moves. As in Medusæ, change of place is effected by the powerful contraction and dilatation of the umbrella-shaped body, like the former, forcing the water suddenly from the cup-like cavity. In the energy and rapidity of the contractions Dr. Hertwig says it is not behind any Medusa, provided the little creature is touched with a glass rod. Under these circumstances it darts, like a rhopalonema, through the water as swiftly as an arrow, by the quickly succeeding pulsations or contractions of its umbrella-shaped body. The strongest contractions were produced by osmic acid. The creature under the action of this reagent becomes bell-shaped, about half as wide across the free border of the bell as it is high. As in Medusæ, the animal has the power of bending portions of the free border of the umbrella inward; or sometimes the opposites halves of the disc become bent toward each other, like the opposite valves of a mollusk.

NEW VOLCANO IN PERU.—A Peruvian newspaper, the *Bolsa*, says that extraordinary phenomena have been observed in connection with the "Corpuna" volcano in the Province of Castilla, which have caused great alarm among the population. The immense banks of snow which have crowned its summit from time immemorial have suddenly melted away with such rapidity as to cause torrents to rush down the sides of the mountain, washing out immense quantities of stones and earth. The river below, being unable to contain the great body of water so suddenly added to it, overflowed its banks, causing great damage and distress. A great chasm or lateral crater next opened on one side, throwing out volumes of smoke and steam as well as tongues of flame, which were distinctly visible at night, accompanied with loud subterranean rumblings. It had never been supposed that Corpuna was or could be a volcano, and there is no tradition that it was ever in a state of eruption. Nor within the memory of man has its crown of snow ever been absent.

NEW CHEMICAL ELEMENT.—It seems probable that a new element will be before long brought to light. Recently, M. Soret found in the ultra-violet spectrum of gadolinite lines which belong to the spectrum of no known metal, thus confirming the opinion expressed some time ago by Marignac and Delafontaine, that gadolinite contained other bases than yttria and the oxides of erbium and terbium.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned

California.

AMADOR.

THE PHENIX.—*Ledger*, July 6: It is rumored that this mine has been sold for $2,000,000. Many improvements have lately been made on this property, among others a saw mill, which saws all the lumber and timber that is used in the mine. This is a great saving, and benefits the company materially in a pecuniary point. In the blacksmith shop the old-fashioned bellows has been dispensed with, the air for the forge being now furnished by steam pressure. It is conveyed through a large pipe in the workshop, from thence by smaller pipes to the different forges. By turning a small faucet or lever a valve is raised, admitting the air in any desired quantity to suit the work in hand; this air is supplied constantly by the motive power that runs the mill. The prospects of this mine never were better than at present.

THE Potosi mill, near Drytown, has been stopped temporarily for want of sufficient water. The rock, however, continues to look as flatteringly as ever.

CALAVERAS.

GWIN MINE.—*Citizen*, July 6: The sinking of the shaft at the Gwin mine is completed and the level—the 1550—is being run. As but a short distance intervenes between the shaft and the chimney, it is expected to have stopes opened within a couple of weeks. In the meantime the stopes of the level above are furnishing an abundance of fair grade ore to keep all the batteries in constant employment.

GOOD RESULT.—The value of the last clean-up of the Thorpe mine was $1,000. This mine is situated at Fourth Crossing, and having free water at hand and every facility for cheap working will undoubtedly prove valuable. It is owned by Messrs. Thorpe, Friedberger, Bode & Co.

INYO.

REX MONTIS.—*Independent*, July 6: This company yesterday shipped a $700 bar of bullion, the result of tailings worked. For the reason that considerable dead work has to be done before ore can be extracted in sufficient quantities to keep the mill running to advantage, it will be several weeks before the mill will start up. The new ore strike at the lowest point of working in the Rex Montis is a vein of 16 inches of ore of an average assay of $400 per ton, selected specimens of the sulphurets and chlorides going as high as $30,000 per ton. Certainly no company could have more incentive to vigorously prosecute work, with such a showing at the bottom.

LOS ANGELES

SANTA ROSA MINES.—*Gazette*, June 29: The first discovery of gold and silver-bearing lodes in the Santa Rosa mining district was made in August, 1877. This district lies in the Santa Ana mountains, to the southeast of Anaheim, and contains a great number of ledges, upon some of which a considerable amount of prospecting work has been done. The ore assays fairly, some of it as high as $200 per ton, bearing both gold and silver. There are now over 100 people in the district, and some 60 mining claims have been located and recorded. A town site has been laid out and a pack train built up the mountain, which is steep and rugged. The district is fairly supplied with wood and water, and seems to have an encouraging future before it.

PLACER.

THE BELL MINE.—*Herald*, July 6: The strike made by Bell in this mine about a year ago which created such a stir at the time, it being one of the biggest strikes made in California for many years, proves to have been simply a small stringer from the main body of gold. After he took out enough last year to do him awhile, he quit work and offered to sell the claim for $20,000. He says it was a lucky thing for him that the parties who talked about buying, but who he now thinks had no other object than to go down in the mine and procure some fine specimens, failed to come to time.

THE Little York company has closed down the Liberty Hill mine for the season, owing to the water failing, but their ground at Little York will run for two months longer. Both mines draw their supply of water from the same source and are under the same management.

SISKIYOU.

QUARTZ VALLEY.—Yreka *Union*, July 6: We learn from A. M. Johnson, that on Saturday last he finished a crushing of 49 tons of quartz from the Lindsey & Co.'s ledge, at his mill in Quartz valley, which cleaned up a little over $80 to the ton. The company has a well-defined ledge and the quartz is rich. Mr. Johnson has also within the past few weeks made another crushing of some 20 tons from his own ledge, which cleaned up $28 to the ton—about $5 per ton better than his last crushing. The Allen Bros. are now getting out some fine rock from their mine. Mr. Johnson has crushed some 150 tons of quartz for them which paid about $15 per ton. The rock they are now getting out is much better, however. There is considerable activity in quartz in that vicinity. The splendid result of the crushings of these two or three mines having awakened the people to a realization of the wealth lying dormant around them, and many more ledges are now being prospected.

AT ORO FINO the water has given out and hydraulicing has perforce stopped for the season, and they have now commenced to clean up. There has not been sufficient ground cleaned up yet to tell just what the yield will be, but it is expected to have been a very good season, as most of the claims have washed away an immense quantity of dirt.

ON LITTLE HUMBUG AND OAK BAR.—Last week Jack Pierson purchased the claim adjoining his own, of its owner, Robt. Smith, for $300. Fred Kohls has sold his claim on Little Humbug to a company of Chinamen. They paid him $600 for the ground. Mr. Walker has also sold his claim opposite Collins' sawmill to a company of Chinamen. We did not hear the price paid for it. The Portuguese company near Oak Bar will start taking out the dust shortly. They are now at work in their claim and have recently built a very large dip wheel. Owing to the lack of current at the point in the river where they put in the wheel, when it started it went the reverse way; this mistake has now been rectified. There is considerable activity reported in mining all along the Klamath river.

TRINITY.

DEADWOOD.—*Journal*, July 6: The prospects of the camp are considered good, Trotter, Dienner & Co., have made a "new discovery" and showed us some rock which will go from $125 to $150 to the ton. Sebastian made a recent clean-up in his arastra, realizing $1,600 from 20 tons of rock. Frick & Davis and Phillips & Willey both have good ledges and are certain of a "big thing."

DONE FOR THE SEASON.—Mr. Fred. G. Haas has finished mining in his Junction City claim for this year, water having failed. We are glad to note that Mr. Haas is entirely satisfied with the result of his season's work, but did not learn the amount taken out.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—Gold Hill *News*, July 10: The south drift on the 1650 level is steadily advancing, the face still in blasting porphyry. It is now in a distance of 170 feet from the north line of the mine. The south lateral drift on the 1850 level is in a distance of 215 feet, the face in hard blasting porphyry. Another crosscut west (No. 4) has been started on this level. The drifts both north and south from No. 2 winze on this level are steadily advancing, the face of each in good ore. The north drift from No. 3 winze on the 1750 level is making good progress. It is now in 82 feet north of the winze. The north drift from No. 2 winze is making good progress, the face in low-grade ore. Repairing the main shaft is making the usual fair rate of progress and will be completed to the 1300 level in about 10 days more. The heat both in the shaft and ore stopes is intense, and greatly interferes with the rapid execution of the work.

CROWN POINT.—The south drifts on both the 500 and 600 levels are being driven vigorously forward to reach a point far enough south for crosscuts to penetrate under where the rich ore was taken out on the upper levels. A drift north from the bottom of the winze on the 2300 level has been started on the west side of the ore vein.

MEXICAN.—The new north lateral drift on the 1600 level has been enlarged, timbered, repaired and a T rail track laid in order to make it what it was intended, a main working passage. At the same time the joint east drift on the north line of the Ophir on this level is being cleaned out, preparatory to again driving it ahead to reach and cut the ore vein.

ALTA.—The new east drift at the 1450 station is being pushed steadily ahead to reach and prospect the ore vein. The north drift on the 1350 level is making good headway, the face in fine quartz and vein matter. The north drift on the 1250 level is also being pushed vigorously forward.

GOULD & CURRY.—The heat is so great and the air so bad on the lower levels that all work in that portion of the mine has been stopped until the large lift pump now being put in at the 1900 level of the main incline is ready to run, and the large 20-inch air pipes from the 1500 level, now being put in down to the 1900 level are ready for use.

OVERMAN.—The south drift from the bottom of the winze on the 1600 level is making good progress, without any valuable change to note.

CALIFORNIA.—The ore stopes on the 1600 and 1650 levels are yielding good ore. A sill floor has been started on the 1750 level for the purpose of commencing ore stopes at that point. The south lateral drift from the winze on that level is in 60 feet, the face in vein matter. Work has been resumed in the north drift from the Consolidated shaft on the 1650 level. A connection has been completed between this drift and crosscut No. 4, which is now being repaired and will soon be again in good working order. This main north drift is now in a distance of 325 feet. The repairs to the main air passages on the 1500 level is still going forward. The repairs to the Consolidated shaft are being pushed ahead with all the speed possible, the great heat still being a constant drawback to the work in all parts of the mine.

CHOLLAR-COMBINATION SHAFT.—No sinking has yet been done. The ropes are now all in good order for sinking to the depth of 3,000 feet. Guides are being put in the pumping compartment of the shaft. The flow of water at the bottom of the shaft appears to be steadily on the increase, having averaged from 65,000 to 70,000 gallons per day for the past week.

BEST & BELCHER.—The joint east crosscut from the bottom of the joint winze on the 1900 level is making favorable progress, the face in hard blasting porphyry. This drift is now in a distance of 42 feet. The south drift on this level from the bottom of the winze is in a distance of 134 feet, the face also in porphyry. This drift is intensely hot and the rate of progress is necessarily much impeded.

SAVAGE.—The greatest feature of interest in this mine during the past week has been the connection of the east drift on the 1640 level with the Sutro tunnel. The blast which completed the connection made a hole about five feet square, through which poured a blast of hot, sickening air, the temperature of which was 110°. This current of hot air rushed with great force up the Savage shaft and out at the top of the ventilators on the top of the building. All work had to be at once suspended in both the Savage drift and the face of the tunnel, in neither of which has anything since been done. The force of the air current is very strong and appears to be increasing. The temperature of both the tunnel and drift is gradually subsiding, that in the drift and Savage shaft having, up to 11 o'clock to-day, fallen four degrees since the opening was made. This tremendous draft of air must soon cool the entire mine and add greatly to the facilities for prospecting the lower levels.

OPHIR.—The northeast drift on the 2000 level is in a distance of 108 feet, the face still in hard porphyry. At a distance of 100 feet from the starting point of this drift, a crosscut, No. 2 east, has been started, which is now in 15 feet, and have from 35 to 40 feet yet to run to reach the ore vein. The milling of 353 tons of the ore taken from the winze while sinking, gave a yield of $38,053, or nearly $108 per ton.

LEVIATHAN.—The north and south lateral drifts on the 750 level are being advanced rapidly through good working ground, and are now in 30 feet each way from main east drift. The north drift is already penetrating a similar character of rock encountered on the 600 level when approaching the ore discovery made on that lead. The drifts are west from and running parallel with the vein. Ten feet have been added to each of the branch drifts.

HALE & NORCROSS.—It is likely that a portion of the air current coming through the Sutro tunnel into the Savage mine will be turned through the connecting drifts into the Hale & Norcross, and create, instead of the downcast current now had, an upcast, which must greatly benefit the ventilation of the lower levels of the mine.

BULLION.—The face of the east drift on the 1840 level is showing more water and a much more favorable appearance of a quartz and ore formation.

UNION CON.—The repairs to the north drift connecting with the Sierra Nevada mine on the 1600 level are making favorable progress. The joint east cross-cut on the Mexican north line is also making steady headway.

TROJAN.—The extraction of ore from the 350 and 400 levels of the mine continues with the usual energy. The ore is of a paying quality, and is being crushed at the Vivian mill on the Carson river, nearly as fast as it is taken out. The ore crushed last month gave a return of between $5,000 and $6,000.

BELCHER.—The main south drift on the 2160 level is steadily advancing, the face in vein matter and showing a greater quantity of good looking quartz. The main east drift on the 2360 level has reached the vicinity of the ore vein, where it has been stopped and a drift started southward on the west side of the vein. The 2360 station is completed, and the north drift on that level, connecting with the Crown Point mine, has been thoroughly timbered and a drain cut for any flow of water that may be encountered in crosscutting that portion of the mine.

SIERRA NEVADA.—Sinking the main south incline has been suspended on account of strong indications of water, which seemed likely to flood the shaft. In order to avoid this, a diamond drill is being run ahead. The last 25 feet of the shaft is in quartz of a very favorable character, in fact the best of any that has ever been found on the lower levels of the mine. Finding so favorable a body of mineral-bearing quartz and a well-defined vein at this depth, is a great encouragement, and gives great assurance that a new ore formation is setting in.

YELLOW JACKET.—The new shaft is down 1,570 feet, bottom in hard, dry ground. About 13,000 gallons of water per day is raised from the shaft, most of which comes in at the depth of 900 and 1,200 feet. The huge new pumping engine has been in motion during the past week and works very smoothly.

JUSTICE.—The north drift on the 1300 level is steadily advancing toward the Lady Washington line. This drift is being run in the west country rock. The south drift recently started on the 1225 level is still advancing, following a small vein of rich ore.

JULIA.—On Saturday last the pump-rod broke, which allowed the water to rise in the 2000 level drift, compelling the stopping of all work on that level.

CON. IMPERIAL.—The two west crosscuts from the main north and south lateral drift on the 2400 level are being pushed vigorously forward, the face of each in vein matter, carrying streaks of quartz, which give low assays.

UTAH.—The northeast drift on the 1150 level is still advancing, the face in hard, dry vein matter. The repairs to the main north and south lateral drifts on the 1350 level are making steady progress.

SILVER HILL.—The main south drift on the 800 level is steadily advancing, the face still in quartz and vein matter. The main east drift on the 900 level is also advancing in very encouraging vein matter.

SUCCOR.—The northwest prospecting drift on the 1050 level is making steady and favorable progress, the indications for the finding of a good ore vein being still excellent.

WARD.—The lengthening of the ropes has been completed and sinking the main shaft is being pushed ahead vigorously with an increased force of men.

LADY WASHINGTON.—The north drift on the 1300 level of the Justice will reach the Lady Washington line in a very few feet more, when crosscuts will at once be started to determine the width and character of the ore vein.

BELMONT DISTRICT.

ABOUT GRANTSTILLE.—Belmont *Courier*, July 6: Part of the new machinery for the new 20-stamp mill is on the ground. The Alexander mine is producing large quantities of good ore, which keeps the mills at Ione and Ellsworth pounding without intermission. This company ships bullion regularly to San Francisco and has a pay day on the 20th of each month. Carpenter and Graham are working on an extension of the Alexander. Their mine is located between Grantsville and Union, and the locators are opening it out as fast as possible. The ditch is dug and waiting for the pipes, these will be laid as fast as they arrive, and will be ready to supply Downeyville with water by the 10th of July. The furnace will be completed before that time but will have to wait for the water. Several men are working in Paradise district for M. San Pedro. This district is about 15 miles west of Grantsville and south of Ellsworth about the same distance. The mines at Ione are not worked and have not been for some time, consequently that camp is quiet. Raymond's mines at Lodi are producing sufficient ore to keep the furnaces steadily employed.

BRISTOL DISTRICT.

HILLSIDE.—Pioche *Record*, June 29: The furnace at this mine started up at three o'clock on Monday afternoon. From that time until Tuesday noon two stoppages had to be made in consequence of things not working right. After that time the furnace commenced working splendidly, and has been going along smoothly ever since; bullion is being turned out at a rapid rate and every one is pleased with the prospect, and the future of the company looks very bright indeed. The furnace is turning out 60 bars per shift, and there are three shifts per day, thus making a run of 180 bars every 24 hours.

ELY DISTRICT.

RAYMOND & ELY.—*Record*, June 29: No change to notice in the workings of this mine. Are still extracting good ore from the upper levels and shipping to mill about 15 tons daily. The bed-plate of the compressor has been ten days on the road from Desert springs, and ought to have arrived. Work on other portions of the machinery is carried on as rapidly as possible.

MEADOW VALLEY.—Continue hoisting screenings from the 2d, 4th and 7th levels in as large quantities as mentioned in our last issue. The mill is steadily at work turning out bullion at a very fair rate.

ALPS MATTERS.—As a majority of the creditors have refused to give them more time, there is hardly a doubt but what the Alps silver mining company will settle their business only by going through bankruptcy. Twenty-four of the miners took possession of the Mazeppa shaft Wednesday afternoon with the intention of working it. The sheriff informed the miners that the mine was under attachment and their work would be for nothing, as they would not be allowed to move anything.

EUREKA DISTRICT.

MT. JACKSON MINE.—*Sentinel*, July 2: The connection between the shaft and tunnel of this mine has been made, and a fine current of air secured for the miners. In sinking the shaft a strata of rich ore was cut, and it is now the intention to work it, running the ore through a chute to a car beneath the shaft. At last, therefore, the desired objects have been successively attained, and in about two weeks the furnaces will be started up and the process of money making begun.

THE EUREKA TUNNEL.—The contractors are in over 300 feet, and still in shale, the indications being favorable for striking the ledge before proceeding much further.

Arizona.

TIPTOP COMPANY.—*Enterprise*, July 2: This company have succeeded in finding abundance of water, by shaft and drift, in the Agua Fria, and will shortly start the mill. The hot, dry weather caused the water to sink beneath the sand and gravel of the creek, hence the necessity of sinking and drifting. The company has plenty of very rich ore at their mill and mines, so lively times are now looked for.

SANTA MARIA DISTRICT.—This district is well watered, has plenty of wood for mining and other purposes; but it is not down there, just now. They have good mines, some of which are pretty well prospected.

HASSAYAMPA.—Doane has suspended operations on the Spaulding mine, temporarily, pending the arrival of a new pump from San Francisco. Native silver has been struck on the Constantine, two and a half miles southeast from Aztlan mill, on main road. On the Gen-

eral Sherman mine, Gormley & Green are taking out rich ore and mine is improving. The U. P., owned by Col. Head, is being worked and is in a flourishing condition. R. Stahl is working on his new mine, just across from Senator. Has a tunnel in 40 feet. The Senator mill started up steam yesterday morning.

MOHAVE COUNTY.—The Mineral Park mill, which has been remodeled and changed hands, is now running on good custom ore. The Hackberry has started up and has about 600 tons of very fine ore on the dump to work. A tunnel in the McCrackin mine caved recently, burying one of the miners to such a depth that no attempt was made to rescue him, as death must have been instantaneous.

THE SEVENTY-SIX MILL.—The mill at Picket Post started up on the 27th ult., is now running steadily and will soon send concentrations via Yuma to San Francisco. It is the best five-stamp mill in Arizona, and runs as easily as a sewing machine, and when the stamps are hung up, the machinery makes as little noise as the turning of a grindstone.

Colorado.

CLEAR CREEK COUNTRY.—*Miner*, June 29: The valuable ore deposits lying on the south-east slope of Republican mountain, directly above the Lebanon tunnel, are shortly to become the center of systematic and vigorous explorations, a company having been lately organized for that purpose, with a capital of $1,200,000, $200,000 of which is set aside for working purposes. The consolidated property comprises 12 claims, which vary in length from 600 to 1,500 feet each. They are contiguous veins, the majority of which have the general direction of lodes in this section, forming a belt about three-fourths of a mile in length. Four of these claims are covered by government patents, and there is not a dollar's worth of incumbrance on any of them. A good deal of work has already been done on this property. Operations will now be actively pushed and reduction works put up at an early day. The ore is of a superior quality, running as high as 600 ounces of silver per ton. Several tunnels start in at different points on the surface of the mountain. The mountain slopes at an angle of 45° along the line of the lodes, offering peculiar advantages for tunneling. From $30,000 to $40,000 was extracted from these veins while working them sufficiently to determine their courses and fulfill legal requirements. Beyond and above the cliffs which form the brow of the mountain, under which the mines are situated, a considerable forest of pines stretches away to the north, presenting an adjunct indispensable to mining operations.

COLUMBIA MOUNTAIN.—In the upper tunnel of the Baltic lode, the lessees have struck two and a half inches of ore. It is about 175 feet above the main level, and carries gray copper, wire silver and other indications of good quality, but no assays or mill runs have yet been made.

THE Peabody is situated near the summit of the mountain. This is a rich lode, some of the mineral assaying as high as 20,000 ounces. There is a large body of mineralized quartz in the discovery shaft, which is about 30 feet deep. The boys have been engaged in tracing it down the mountain for some time, and are now 400 feet east of the discovery.

NEW SMELTING WORKS.—San Juan *Prospector*, June 29: The Cooke Bros. are going on with the erection of reduction works on the Animas, at the mouth of Boulder gulch, near Silverton. Joe Reef will have charge of the work, and it will be pushed forward as rapidly as possible. The site is said to be a very desirable one, as it will be convenient to the ore-producing mines on Hazleton, Solomon and Round mountains, and from the upper Animas and Cunningham gulch. The Animas river will be dammed, and a flume and ditch constructed, by which a splendid water power will be secured. The works will be constructed to reduce ores from all the mines from which they can purchase the ore, but for the North Star mine in particular, which is owned almost exclusively by Crooke Bros. This enterprising firm will do a good deal towards the rapid development of Silverton and vicinity, and it seems to us have shown sound judgement in putting up works where ore can be had in any desired quantity. They have at their command an almost unlimited amount of capital, and can go ahead with any enterprise where money is needed.

Dakota.

BLACK HILLS.—*Journal*, June 29: The placers about Deadman's gulch, Rockerville and Hayward are likely to equal any yet found in the Hills, many men are making fair wages there and some are doing remarkably well. The more they are prospected the more extensive the diggings appear to be. Probably the most valuable discovery that has been made is in a gulch two miles northeast of Rockerville, in the limestone formation, and probably nobody other than a tenderfoot or a woman would have stuck a pick in the ground at that point. The exploit of a pilgrim from the States, who recently wandered into that locality, and found it yielding $1.80 to the pan, and shortly thereafter sold his third interest for $1,500, has been already told in these columns. West of this belt of mines comes a different formation, and where true fissure veins are found. In any direction are found quartz and placer mines, and the only trouble experienced is the lack of capital for their development. Those miners already on the ground, have from 10 to 100 leads each, which absorb all the time and money they have to represent and hold their claims. The great drawback of the country is that there are too many mines, and too few practical miners. But these difficulties will soon be obviated with the speedy advent of capital. Ditches will be constructed to the thousands of acres of rich placer diggings; hundreds of mills will be in operation, and constant employment guaranteed to thousands of men and teams. Then the southern and central portions of the Hills will take its proper place as the foremost mining camp in the known gold and silver-producing countries of the world.

Idaho.

MILLER DISTRICT.—*World*, July 2: The diggings in this district lie about 13 miles northwesterly from Bauuer, on the summit of a high mountain, where some work had been done in early days. The spot found by Mr. Graham was small, but it is thought there is more rich ground in that vicinity. On the summit of the mountain are a few flats, from which there are gulches leading down a steep and rugged mountain side. Several men are prospecting there and hope to find placer ground in some of them. At Dry lakes, near by, George Doble and another man have found some ground that they think will pay to rock. A sufficient quantity of water for sluicing can be had only in the early spring, and then but a short time. This will be a great drawback to the successful working of the diggings that may be discovered unless they are rich enough to be worked with a rocker. The gold taken out is richer than the average in this county, and as it is found on the highest mountain of that section, it is probable that a very rich ledge crosses it. Where the gold is found large quantities of quartz are scattered over the surface. The country is favorable for the successful working of quartz, the mountain sides being steep, so that any desirable depth could easily be obtained, and an abundance of timber.

FROM YANKEE FORK.—A gold-bearing lode has been discovered on Ester's mountain, about six miles from Bonanza City. On the surface it is 16 or 18 inches wide, but is not so wide at a depth of several feet, although fully as rich as on the surface. The discoverers pounded out $300 in a hand mortar. A rich piece of placer ground was found late last fall on the opposite side of the river from Stanley Basin. The proprietor has succeeded in getting water on it, and is making money. All the pack-trains in that country are engaged at packing rock to Round valley, from where it will be shipped in wagons to the railroad, thence to Salt Lake City, where it is sold. Lemhi county will not advance to any great extent this year, as no mills have yet been shipped there. The proposed military road would be a great benefit to that county, and the people are anxious to have it put through. The ledge that Amos Franklin discovered on Loon creek last winter is looking splendid.

Montana.

ORE SHIPMENTS.—*Butte Miner*, June 25: Every day during the last week lines of wagons could be seen pulling out from the Original lode claims heavily loaded with ore for the terminus of the Utah Northern. The week's shipments from the Gonyon, aggregate 80 tons, while something over 40 tons was the amount shipped from W. A. Clark's Discovery claim. Newark, New Jersey, is the destination of the greater part of this ore, but some of it goes much further, to Freiberg or Swansea, we are informed.

PENOBSCOT MINE.—There is on exhibition at L. H. Hersfield & Bro.'s bank, a gold bar, weighing 1,429 ounces, fineness .775 and of the value of $23,272, being principally the product of an arastra, which has worked regularly during the last two weeks on ore from the Penobscot mine. It was cast at Molitor's assay office. This bar will be kept here for a day or two, after which it will be forwarded to New York as evidence that the $54,000 and $20,000 bricks from the Penobscot, lately shipped there, has not exhausted the richness of the mine. The mill ordered for the Penobscot, from Frazer & Chalmers, Chicago, has arrived on the ground—the mill-house has been erected, and the stamps will soon be in motion. With adequate milling facilities, the Penobscot will yield such an abundance of gold as will give it rank among the most valuable gold mines in the world.

Utah.

ORE SHIPMENTS.—Salt Lake *Tribune*, June 29: Notice was made the other day of a three car load shipment of ore from the Elmoray mine, on the Sunheam lode, in Tintic. This lot of ore was sampled, assayed and placed on the market yesterday. The assays show the first-class ore, a lot of three tons, to be worth $899 per ton; 16 tons of second-class ore, worth $185 per ton, and 11 tons worth $80. The mine from which this shipment was made is looking very well, it being down by a main incline, a depth of 150 feet, and showing a fine vein of ore in the bottom. Shipments from the Elmoray may now be looked for about once in every 30 days, and in the meantime mining matters in Tintic are coming to the front, especially on the claims along the Sunheam lode. All the ore now being shipped to the smelters from the Cottonwoode and Bingham, is high grade.

PARK CITY.—Salt Lake *Tribune*, July 4: A rich strike has been made in the White Pine and Washington claim which could not now be bought for $25,000. This claim has been opened at intervals for 2,000 feet, showing a hanging wall of rotten porphyry. It is unbroken for that distance, and carries the water on the vein at 30 feet from the surface for that distance. Immediately below and outside the fissure it is dry for 100 feet down. The first extension southwest is the Utah, into which a tunnel is now being excavated to tap the ore body 200 feet deeper than the Washington and White Pine have it. The face is supposed to be within 25 feet of the ore body. The Mohawk, or Secoud Extension, is 1,200 feet distant. It has a shaft 70 feet deep, the same vein, walls, and everything corresponding with the White Pine, so that the Utah stands a moderately sure chance of ore lying between the two, and the additional chance for drainage for the upper 500 feet of the mine. Other good prospects in the neighborhood look very promising. The Pioneer, 1,000 feet west, crosses the ridge at the same angle as the above. It has been reached with a tunnel that taps the vein 1,000 feet below the summit. Lying west of this again, at half a mile distant, is the Central and Iron Horse, crossing the ridge at the same angle. There are three parallel fissure veins presenting the same character of ore, walls and country rock. All have shown good ore on the summit, but more or less broken up, as the elevation is over 9,000 feet, but with the tunnels tapping them low down, which have been quietly running for two years, we expect to take away the reproach of a "one ledge district." John the Revelator, shows ore that assay $118 per ton. The Great Basin tunnel company are also running a drift to strike the White Pine on the east. The Empire company also seem in earnest, and have a large force of men building, hauling, making roads and opening some of their numerous claims.

News in Brief.

ISAAC FRIEDLANDER, the well-known capitalist, died in this city on Thursday morning.

THE grape crop in Sonoma county promises to be large.

A RIDER has been killed at the Long Branch races.

SENATOR BOOTH is expected at Sacramento by August 1st.

YOUNG FREMONT is to be his father's Secretary in Arizona.

THE army worm has appeared in the vicinity of Woodland, Yolo county.

KING HUMBERT and young Menotti Garibaldi are the best of friends.

THE aggregate appropriations made by the last Congress is $157,203,933.

THE bonanza mines have turned out $100,000,000 in gold and silver bullion.

GENERAL FREMONT'S salary as Governor of Arizona will be $2,500 per year.

MANY fatal cases of sun-stroke are occurring in the East, also a few in California.

THOMAS LOWE of Coos Bay, has a second crop of potatoes ready for market.

A MAN named Charles Whittier, a cousin of the poet, died lately at Downieville, Cal.

IN New York, July 6th, Dr. Carver broke 99 out of 100 glass balls thrown in the air.

THE new Mormon temple in Salt Lake, now being built of granite, will cost $5,000,000.

THE army worm is said to be destroying the Dungeness, Washington Territory, potatoes.

TWENTY Nez Perce Indians have been organized at Fort Lapwai as scouts for Howard.

MAJOR DOWNIE, after whom Downieville, California, was named, is visiting Virginia City.

THE waters of Tulare lake, California, are higher this year than during the past 15 years.

A NEW chicory factory has been recently built on Braudt's ranch on the San Joaquin river.

AUGUSTUS HARTSO was killed by a caving of earth in a mine at Blackfoot, Montana, recently.

ANOTHER "fan-tan" house is to be built in Chinatown, at Reno. The license for the game is $400 per quarter.

A FARMER named James Francis, near Victoria, B. C., while felling a tree, was struck by a branch and killed.

THE Nihilists in Russia show their contempt for religion by smoking cigarettes in catbedrals and churches.

WILLIAM CULLEN BRYANT left property valued at half a million and had an annual income of about $10,000.

BY order of the Secretary of War the United States army is to be recruited up to its full force—25,000 men.

TEXAS claims to have 3,000,000 inhabitants, and to be the third in population and the first in size of the States in the Union.

JOHN O'SHEA, Coroner of Lake county for the past eight years, was drowned in Soda bay near Lakeport, last week.

THE campaign against the Cubans cost the Spaniards 80,000 men, and the island is represented as a vast cemetery.

TOM THORP, while drunk at Gridley, Butte county, fell from a horse and fractured his skull, and died a few hours afterwards.

THE Chief of Police announces that since the new police has been assigned to duty but few burglaries are reported.

DR. JAMES AYER, the patent medicine man, died, last week, in Massachusetts, worth a good many millions.

THE wheat crop the coming year in the United States will reach the large sum of 400,000,000 bushels.

FOUR or five white laundries have been started in San Rafael, but there are none now, and John holds the fort.

WHILE bathing at Skowhegan, Me., Osgood Willey attempted to rescue his son, who got beyond his depth. Both were drowned.

THE San Beruardino *Times* says there is no market for honey in that town. The finest white sage, in section boxes, can hardly be given away.

LAST week, C. F. Germann, a shift boss at the Caledonia mine, at Gold Hill, fell to the bottom of the shaft, a distance of 1,450 feet, and was torn to shreds.

Advices from Bolivia state that much suffering exists in Cochabamba. The usual rains have not fallen, and the crops are destroyed.

THE steamer *J. B. Walker*, for Constantinople, is now ready for sea at New Haven, with a cargo of war material valued at $2,000,000.

THOUGH hundreds have been punished for publicly regretting the failure of the attempts against Emperor William's life, there is still no cessation of similar offenses.

A MAN named Anglum, at Chile gulch, Calaveras county, on the Fourth held an ignited giant powder cap too long, when it exploded and blew his hand off at the wrist.

THE condition of affairs on the Mexican border is regarded as very serious by the Government, and will receive attention at an early meeting of the Cabinet.

PERU has for the first time indulged in a census, which gives the population as 2,699,945, of whom 1,365,045 are males; 100 men to 98 women.

OIL has been struck at a depth of about 1,000 feet in the well of the Los Angeles Oil Company, Sespe district. It yields 30 barrels per day of a fine quality of oil.

THE spring clip of wool of Arizona Territory is estimated at 1,000,000 pounds, value between $120,000 and $150,000, after deducting cost of shearing, sacking and marketing.

No fireworks were allowed in the public parks of New York on the last Fourth of July, whereby much expense to the city was saved, and the losses by fire greatly diminished.

POPE LEO, after first making friendly overtures to the Emperor of Germany, has, by the advice of the ecclesiastics surrounding him, determined to adhere to the policy of Pius IX.

AN article will be introduced in the Constitution about to framed in Washington Territory limiting the amount of land which may be acquired or held by any individual or corporation.

JOHN MESSINGER, near Hillsboro, Oregon, fell from the top of a fir tree which he was trimming, a distance of 80 feet, crushing him horribly. He was a fleshy man, weighing about 200 pounds.

WM. WATT, a well-known miner and a prominent citizen of Nevada county and the State, died at North Bloomfield, on Saturday last, from injuries received by being thrown from a carriage a few days before.

PITTSBURG was visited by a severe storm on the Fourth. Several houses were struck by lightning, and in the rural districts houses and bridges were washed away, and crops greatly damaged.

THERE were 76 deaths in the city last week. For the corresponding week last year there were 78 deaths, and the average weekly mortality the corresponding weeks the past five years was 87.

A PAPER has been posted in all cotton mills of Stockport district, England, giving a fortnight's notice of 5% reduction in wages. Operatives seem to favor resistance. A strike there would affect 25,000 people.

"MOLLIE MCCARTHY," the California mare that ran against the horse "Ten Broeck," over the Louisville track, July Fourth, broke down and was distanced. Both animals were badly used up.

THE country east of the Cascade range, in Washington Territory, is settling up fast. The records of the Walla Walla Land Office show that upwards of 300,000 acres of land have been entered during the past year.

LAST week, Numa Dupera, of San Francisco, aged 16 years, who was spending his vacation at Noyo, in Mendocino county, had his neck broken. He was searching for eggs on the edge of a cliff and fell a distance of 45 feet.

JOE MARTIN, aged 13, of Haywards, Alameda county, had his right hand shockingly torn, and his eyes, face and bare legs badly burned, by the explosion of a flask of powder on the Fourth. Frank and Manuel Thomas aged seven and three years, were also considerably burned.

JOHN A. SWAN, a pioneer of Monterey, an Englishman by birth, says in his autobiography: "All my share of the gold and land in California, after 35 years passed on the Pacific slope, is an old adobe house in Monterey, once the first theater in California, with a lot attached to it."

A REPORT from Anaheim, Los Angeles county, says: The cut and wire-worms have entirely disappeared. The corn crops are looking splendid. The barley crop has been entirely exaggerated; it will not yield more than five sacks to the acre. The rye crop will prove most remunerative of all.

ACCORDING to the latest returns, the cultivated land of France is divided into 5,500,000 properties. Five millions are under six acres. Belgium has a like subdivision of property. In Ireland, on the other hand, 110 owners hold more than one-fifth of the soil.

A Great Engineering Feat.

The new railway bridge over the river Tay was opened with much ceremony on the 31st of May. The first movement to bridge the Tay was made about 40 years ago hy the Edinburgh and Northern (afterwards the Edinburgh, Perth and Dundee) Company. It was not till 1871, however, that a project destined to he fulfilled was initiated. In 1870 the necessary act of Parliament was obtained, and on the 8th of May of the following year the contract for the erection was signed. The contract was transferred in 1873 to Messrs. Hopkins, Gilkes & Co., of Middlesborough; and Mr. A. Grothe, who was engineer and manager to Mr. De Bergue, and had shown very great professional skill in the manner in which he proceeded to erect so gigantic a structure was continued by the new contractors, and the admirable, thoroughly substantial bridge which now spans the river is a proof of their wisdom in taking Mr. Grothe into their service. The bridge is 10,612 feet in length—or two miles and 52 feet—and is thus the longest railway bridge over a running stream in the world. The Victoria bridge, Montreal, comes next in respect to length, being 9,194 feet, or 1,418 feet shorter than the Tay bridge. A still more extraordinary bridge than either is one on the Mobile and Montgomery railroad, called the Tensas and Mobile bridge, which is 15 miles in length; but as the greater part of it is carried over immense morasses, it cannot be fairly compared with the Tay bridge, which spans a tidal river.

The bridge starts from the Fife side of the Tay, where the land is about 70 feet above high water, and gradually rises at a gradient of one in 356 until the highest part of the bridge is reached, being 130 feet from the level of the rails to high-water mark. The greatest altitude occurs at the center of the large spans, and from this point towards the north side there is a sharply falling gradient of one in 74. In the structure there are 85 spans of the following dimensions: Eleven spans of 245 feet each, two spans of 227 feet each, one span of 166 feet, one span of 162 feet 10 inches, 13 spans of 145 feet each, ten spans of 120 feet 3 inches each, eleven spans of 129 feet each, two spans of 87 feet each, 24 spans of 67 feet 6 inches each, three spans of 67 feet each, one span of 66 feet 8 inches, six spans of 28 feet 11 inches each. All the spans, with the exception of that of 166 feet, which is made by a bowstring girder, are formed of lattice girders, but in addition to these spans, there are adjoining the north end of the bridge: one span of 100 feet, bowstring girders, one span of 29 feet, plate girders. The 13 largest girders, each being about 200 tons in weight, are in the center of the bridge, and over the navigable part of the river. The girders are arranged in continuous groups, with proper provision for expansion, and are all supported on piers of varied construction. The permanent way consists of double-headed steel rails, fished at the joints in 24 feet-lengths, weighing 75 pounds to the yard, and secured by oak keys in cast-iron chairs. The chairs are fixed at intervals of about 3 feet to longitudinal timbers 17 inches wide, and varying in depth from 7 to 14 inches.

Throughout the whole length of the bridge each rail is provided with a guard-rail to afford additional security to trains passing over the structure. The floor of the bridge consists of three-inch planking, and is covered with a waterproof composition. On both sides of the bridge, for its whole length, a strong handrail is erected, and painted in a light blue color. The foundation of the piers are formed of iron cylinders, with brickwork and cement. Fourteen piers at the south side are built entirely of brick, and on rock foundation, and consists of two cylinders of nine feet six inches in diameter, connected by a wall of brickwork three feet in width. At the 14th pier it was found that the rock suddenly shelved away to a great depth, under beds of clay, gravel and sand, and therefore another kind of pier had to be resorted to which would give an equally sure footing. The weight of the pier was lightened by substituting for the heavy brickwork above high water cast iron columns, fixed together hy horizontal and diagonal transverse bracing, and the cylinders were increased to 15 feet in diameter. The whole of the piers after the 14th are built in this manner, but in the case of the highest piers, supporting the 245 feet spans, they have a cylindrical base of iron and brick in cement 31 feet in diameter, and from 40 to 45 feet in depth, standing a few feet above high water. The whole of the cylinders supporting iron columns are finished with a coping of Carmyllie stone. The first stone was laid on the Fifeshire side on the 22d of July, 1871, and on September 25th, 1877, six years afterwards, the directors and engineers had the satisfaction of crossing over the bridge for the first time in a train.

The contract price of the bridge was £217,000, but the actual cost is £350,000, the great increase being caused because of the original plans of the piers having to be departed from, and plans prepared of another description of piers adapted to the soil in the bottom of the river. The quantities of materials used in the structure are as follows:—3,520 tons of cast iron, 6,281 tons of malleable iron, 90,600 cubic feet of timber, 8,600 of cement, 4,350,000 bricks, 27,000 cubic feet of dressed ashlar, and 355 cubic yards of rough ashlar. The engineers engaged in the construction of the bridge were: Messrs. Alfred Grothe (superintending engineer), Frederick W. Reeves, G. G. Lawrence, R. S. Jones, Theodore D. Delprat, and Thomas Templeton. On Mr. Grothe devolved the responsibility of carrying out the works, and he has done so with remarkable success.—*Iron.*

Paraff's Process.

The Valparaiso *Mercury* contains the following in regard to the result of the legal proceedings instituted against this well-known individual:

The celebrated Paraff process is about to be brought to a conclusion. Although we have frequently spoken of this affair, yet we do not think it will he useless to give an idea of the causes that originated it.

It is now about two years since Paraff said that he was the inventor of an unknown system for working gold, by means of which he extracted a considerable quantity of this metal from ores in which scarcely a particle was found when assayed by the process followed up to that time.

In order to carry out his discovery, two companies were formed in Santiago, which spent considerable sums, without the partners being able to obtain any benefit from the famous reagent, except when Paraff or Rogele took part in the operation.

The downfall of the business caused so much to be talked about it, that the fiscal presented himself and accused Pariff of deception and cheating, and Rogele of having acted in concert with the former to sustain and convince in the existence of a false reagent, and of being he who vitiated the operations with the gold which he threw into the crucibles and coppels.

The course of the action has gone on slowly, and meanwhile the presumed culprits are in prison.

The sumaria being at last terminated, the fiscal's report was presented, and after making an extensive review of the motives for the accusation and the charges brought against Paraff and Rogele, he concludes by requesting that the cause he considered as terminated and the two prisoners be set at liberty, there being no further ground of accusation against them. Since this sentence Paraff has requested to be set at liberty under bail, but the Judge has refused his request. The sentence is expected from one moment to another, unless fresh incidents arise to complicate this long affair.

Red Canyon Placer Mines.—The *News* of last evening has the following in regard to a discovery made by a party of Slippery Gulchers: J. F. Colbath and John Ryan have returned from Silver Lake mining district. In this district, about four miles north of Red canyon, is a promising placer claim, which is owned by eight Gold Hillers. Messrs. Colbath and Ryan brought some specimens with them. The work of development has not yet commenced in earnest. Twelve buckets of dirt from the surface were worked with a rocker, yielding nearly $2 50 in coarse gold. Some of the pieces are nearly as large as a bean. Two men, Henry Peal and William Sibley, were left to look after things on the claim. The locators of this property are well satisfied with the prospects, all of them expecting to become millionaires before long. The only drawback is a scarcity of water, but this will doubtless be removed when full development of the richness is shown. The diggings are about forty miles from Gold Hill. —*Territorial Enterprise.*

The Mines of Dun Glen.—Quite a revival of the mining industry has taken place says the *Silver State*, in Sierra district, Humboldt county, Nevada, since Col. Dave Buel started in there a few months ago. The ten-stamp mill at Dun Glen is running splendidly and successfully. One of the batteries—five stamps—is crushing gold ore from the Lang Syne mine, and the other is crushing silver ore from the Wentworth and Wright mine. The silver ore is worked by wet process up to 82% of its assayed value, and the bullion is over 990 fine. The first shipment of bullion will be made next week. The mines are looking well and the future now seems bright and promising for the old camp.

De Frees Mine.—On Wednesday last this company shipped four bars of bullion of the value of $7,102.67. The De Frees company commenced crushing their ore with their own mill on the 18th instant, and the above shipment includes the entire "strainings," or clean-up, of the concern till Monday last. In addition to this the amalgamators at the mill retorted 230 pounds of bullion yesterday, which is still at the mill. The above statement and figures ought to be pleasant reading to the holders of De Frees stock, this property having been under a cloud since last fall. The showing is tiptop for a week's run with only ten stamps.

A New Railroad in Russia.—It has been announced that the emperor of Russia has approved of the project for a railway from Orenburg to Central Asia, a project which, if carried out, would greatly strengthen the power of Russia in the east. The principal difficulty promises to be a financial one. The total length of the line is over 1,300 miles. This is five times the length of the line from St. Petersburg to Moscow, yet the construction of the latter line necessitated loans to the amount of $207,000,000. Should the projected railway be costly in proportion, it is thought to be doubtful whether Russia could find the capital for its construction.

A Resurrected Mining Region.

Some 14 years ago, a great many mineral-bearing lodes were discovered in the section of country that now constitutes the westerly portion of Nye county, Nevada, drawing into it quite a large population, the most of whom afterwards abandoned it. Lately a number of these lodes have been more thoroughly explored, and some of them seem to be turning out well.

A correspondent of the Belleville *Times* says the Alexander mine, at Grantsville, is keeping two mills running steadily, and that Downeyville is a camp of monster proportions, in a mineral sense, having the richest smelting mine in Nevada. He adds: Here I found a new water-jacket furnace which will be ready to run in five days, 30 houses, stores, saloons, feed stables, coal-burners, brick-makers and prospectors, all engaged in the development of this rich and extensive property; stage lines, Wells, Fargo & Co.'s express, and a new and direct route opened to Wadsworth by Mr. Bell, shortening the distance to less than 100 miles, all of which goes to show the implicit confidence that is placed in the camp. They have something over 2,000 tons of rich smelting ore on the dump. This rich and extensive property is owned and controlled by the Downey Brothers, discoverers of the same.

Mrs. McMurphy, of Spanish belt fame, is the owner of what promises to be a very rich and valuable mine, located on "the extension" of the Alexander lode. It is said there is plenty of ore in sight, which, so far as tried, assays from $250 to $2,000 per ton.

Cast and Wrought Iron Water Piping.—The Hessen *Gewerbeblatt* remarks that it is well known that iron rich in carbon is less subject to oxidation than iron poor in carbon. Wrought iron therefore, exposed to influences which promote oxidation, rusts more rapidly than cast iron. The very simple experiment of laying samples of both sorts in damp earth and leaving them there for a sufficient time will show the difference in their rates of rusting. The duration of wrought piping when laid is thus likely to be less than that of cast piping, and this is proved to be the fact in practice. Commonly speaking, the temperatures of water running through piping in use is lower than that of surrounding bodies, and the walls of the tube are constantly condensing moisture, which powerfully promotes rusting. In house, or in masonry conduits, where the pipes can be got at and kept protected, by tarring, painting or otherwise, from rust, wrought iron tubing can be used with advantage; but in earth it is otherwise. An experienced engineer, who has often had to lay wrought iron piping in short lengths below ground, has always found them, before long, more or less destroyed.

The Cariboo Labor Market.—We mean to repeat what we urged in early spring; Cariboo is in no condition to receive accessions to her laboring population, and will not be until the lodes have proved to be remunerative. Until crushing shall have fairly commenced there will be no field at Cariboo for workingmen. The number of laborers of all kinds already there is larger than can find employment. It would be madness for people without some capital to go to the mines expecting to find a situation awaiting them. Some who have gone in spite of our warning are writing back to friends in California that Cariboo is no place for a poor man. If people will put their hands in the fire after they have been warned to keep them out, is it any wonder they are burned? Men without capital should seek employment near the coast until the time arrives when they may have a reasonable chance of getting work at the mines.—*Colonist (B. C.)*

A New Salt Mine.—Two car-loads of salt arrived here yesterday morning from the works of the Desert Salt Company, on the line of the Central Pacific railroad, near White Plains station. These works are owned by W. Smith & Bro. and Joe Moran, who located the salt field some years ago and are now just getting everything in good shape for producing salt in large quantities. They have springs on an elevated piece of ground, the brine from which may be run to evaporating vats in all directions. Their salt is as white as snow and is chemically pure. If ground it would make an excellent table salt. The salt which arrived here yesterday was consigned to J. B. Mallon, who is the agent of the compay in this city.—*Territorial Enterprise.*

At Last.—The Esmeralda *Herald* learns from ex-Governor Blasdel that the mines at Rockland, on East Walker river, Nevada, are looking remarkably well. His mine at that place shipped the first bar of bullion last week. There are two arastras working an old mine on East Walker river that was discovered as early as 1858—before the discovery of the Comstock. They are taking out considerable bullion. In fact, all the mines on East Walker river are looking well, and that section bids fair to become one among the noted in Nevada.

Tybo District, Nevada.—In Tybo times are lively. The mines never looked better, and are furnishing sufficient ore to keep the works running to their full capacity. Vast quantities of lead are placed up at the refinery awaiting transportation to the railroad, and everything in and around the town indicates a permanent prosperity.

The Engineer.

The State Survey.

We spent a couple of hours very pleasantly on Saturday, says Col. Schuyler in the Stockton *Independent*, at the camp of the State Engineer corps, a short distance down the Stockton channel, inspecting their instruments and general outfit. We cannot enough admire the thoroughness of detail with which Mr. Hall, the efficient State Engineer, has made all his arrangements for prosecuting the work which the Legislature has laid out for him. Stockton has been made a rendezvous as a convenient starting point for the river parties who are to make a detailed survey of the two great rivers of the State. Two floating arks have been built, at a cost of about $900, each adequate to the accommodation of a large party. Each contains a stove and complete kitchen equipment, a long table with folding sides, for dining and drafting purposes, two rows of bunks on the sides, and a locker for each man's baggage underneath the bunks. With these arks and their small boats and the steam launch for towing them about, the parties can thread the rivers and their adjacent sloughs with ease and comfort, having a most commodious home in the midst of the most inhospitable swamp they may chance to be in. For a week or two past they have been regulating the self-registering tide gauges and current meters, and are now ready for work. One party started Saturday night just after we left the camp, to commence work at the head of Old river, a few miles below the railroad bridge. They will make a careful meander of the river, taking cross sections at frequent intervals. No chaining will be done, but all measurements will be taken by means of stadia rods, and a micrometer arrangement of the transit. The notes of the survey will be plotted upon a map right on the ground by a topographer, who will note and sketch in the contour of the river and surrounding country as it appears to him on the spot. Mr. Kluegel will have charge of the party and run the transit, Mr. E. E. Tucker will act as leveler, Mr. E. Grunsky as topographer, and Mr. Frank Soule as rodman for the leveler. There will be three stadia rodmen, besides boatmen, axmen, etc. They will be followed by a hydrographic party who will make observations on the currents, tides, etc. Mr. Boschke starts with the other ark and a full party for the Sacramento river in a few days. At the camp we saw six of the self-registering tide gauges, three of which are to be placed on the San Joaquin below Stockton, and three on the Sacramento. Six more have been ordered. They are very simple, being run by clock work that rolls out a sheet of endless paper at the rate of an inch an hour. A float is so connected with the mechanism by a cord and pulley that a pencil is moved across the paper as it moves, making a diagonal line with the rise and fall of the tide, and registering the state of the tide at every hour or fraction thereof. The only attention they require is to be wound up once a day. They are enclosed in a box which is placed upon a wharf, or in some place where the tube containing the float may be let down into the water. They are of a pattern designed by Mr. Hall, and cost only one-third the price of those in ordinary use. The current meters are beautiful instruments and work at any desired depth. When the survey is complete the exact condition of the rivers in all their parts will be known, and with that information the correction of their weakness may be more intelligently planned. Mr. Warfield, one of Mr. Hall's principal assistants, has gone to Fresno to commence the survey of the irrigation districts of the valley. These surveys, which should have been made years ago, will be watched with interest and the results impatiently looked for.

Comparative Cost of Freight and Passenger Traffic.

We take the following from a paper hy Mr. Francis R. Conder, read before the institution of mechanical engineers, London: On seven leading French railways in 1872, the average cost of conveying 100 tons of loaded train for one mile was 25.4d. The average tare of the passenger trains was 94.5% of the gross load; that of the non-passenger trains was 61.5% of the gross load. It results that to carry a passenger for a mile cost 0.306d.; and that to carry a ton of freight for a mile cost 0.66d. On seven principal railways in 1875, the average cost of conveying 100 tons of loaded train was 26.6d. The average tare of the passenger trains was 82.2, that of non-passenger trains 67.3% of the gross load. The resulting cost of conveying a passenger for a mile was 0.15d.; that of a ton of goods 0.813d. On seven American railways in 1873, according to details contained in the "Investigation into the Cost of Passenger Traffic on American Railroads," by Albert Fink, C. E., the average cost of conveying 100 tons of loaded train for a mile was 50.7d. The average tare of the passenger trains was 93.14%; that of the non-passenger trains 58.37% of gross load. Thus the conveyance of a passenger per mile cost 0.493d., and that of a ton of goods 1.57d. Prices have since been reduced fully 30% in America. On 460 miles of railway in New South Wales in 1876 (according to the report of the government commissioner) the average cost of conveying 100 tons of loaded train for one mile was 55.8d. The average tare of the pas-

senger trains was 93.04 %; that of the non-passenger trains 65.09 % of the gross load. The resulting cost of conveying a passenger for a mile was 0.534d., and a ton of goods 1.598d. Omitting the passenger traffic of India, as exceptionally advantageous to the carrier, the average outcome of the above figures is that a train of 100 tons gross weight conveys either 35 tons of goods or 96 passengers; so that, subject as before provided to verification from accurate accounts, the cost of the conveyance of a ton of goods is equal that of the conveyance of 2.74 passengers. It follows that in order to derive an equal proportionate profit from passenger and non-passenger traffic, the freight per ton on the average of the lines in question should equal 2.74 times the average fare of a single passenger for equal distances.

Proposed Railway to Yellowstone Park.

The *Railway Age* looks with distrust upon a project mooted in Omaha. A company has been incorporated in Nebraska with the ambitious object of building a railway to be called the Omaha & National Park railway, from Omaha via the Niobrara valley to Yellowstone park. This great national pleasure ground, it may be necessary to remind our readers, lies in the northwestern corner of Wyoming Territory, and is a tract of land 55x65 miles in extent, near the center of which lies the Yellowstone lake, a body of water 15x22 miles in size, with an elevation of 7,427 feet above the sea. This region, which has wisely been set apart by Congress for the public, comprises some of the most sublime and astonishing natural features to be found on the earth, and in the course of time as the means of access are improved, it will be the resort of wonder seekers from the four quarters of the globe. The project of a railway from Omaha, however, is almost chimerical. The distance is at least 800 miles, and while the route up to the Niobrara valley nearly to the Wyoming line is practicable, the remaining half of the distance is largely a wild, mountainous, barren, unpeopled country, through which a railway will be, for decades at least, only a dream. It is not supposable that the projectors of the "Omaha & National Park railway" think seriously of such a destination as the name indicates. The National park, however, will, before many years, be accessible without difficulty, as the proposed line of the Northern Pacific railway runs up the Yellowstone river through Montana, to within 50 miles or so of the Wyoming line, and the prospects for the completion of that great enterprise now seem encouraging.

Lighting and Extinguishing Street Lamps by Electricity.—It may be that the days of the lamp-lighter are numbered. At a recent meeting of the English Society of Engineers, a paper was read by Mr. St. George Lane Fox, on "The Lighting and Extinction of Gas by Means of Electricity." The author commenced by alluding to what had already been attempted in this direction, with special reference to the pneumatic system proposed some time ago, in which an extra pressure in the gas mains was made to act upon an apparatus provided for each lamp. He then explained the difficulties that presented themselves, and which led him to design the electric system, which he proceeded to explain. In this system the lamps to be operated upon are connected together by an insulated wire, so that electric impulses sent from one point or station will operate simultaneously on every lamp in the circuit, through the instrumentality of an apparatus with which every lamp is provided, so as to turn the gas on or off independently at any burner, and also to light it. The lamp apparatus consists chiefly of a small induction coil which produces the spark for lighting the gas at the burner, and the soft iron core of this coil supplies, in conjunction with a permanent magnet, the necessary force for opening and closing a valve of peculiar construction, which forms a special feature of the invention. Taking a district of 3,000 lamps, placed 45 yards apart, he estimated the first cost of the system with overhead wires at £4,886 15s., and that of the system with underground wires at £7,499 5s. The cost of working was placed at 4s. per lamp per annum, for cleaning, lighting and extinguishing, equal to £600 per annum. The cost of working on the ordinary system, as per estimates supplied by the gas companies, was stated to be 18s. per lamp per annum, or equal to £2,700.

The Cost of the Canadian Pacific.—The total cost of the Canadian Pacific railway is estimated at $100,000,000, divided as follows: Lake Nipissing to lake Superior, $23,000,000; lake Superior to Red river, $14,700,000; Red river to Rocky mountains, $26,000,000; Rocky mountains to Pacific, $35,000,000; Pembina branch, $1,300,000. But, says the *Railway Age*, the vast sum of $15,000,000 has already been expended in surveys and contracts, and all there is now to show for it is some 70 miles of track from Thunder bay on lake Superior westward into the wilderness, and a few miles of track from Winnipeg, in Manitoba, eastward. The cost of the Union and Central Pacific roads with equipment was about $250,000,000, and these lines are much shorter than that of the Canadian Pacific, and for a large part of the distance are through a much easier country. It is true that railways can now be constructed much more cheaply than 10 years ago, but it is not at all likely that the Canadian enterprise will be confined to the limits of the original estimate. That it will eventually be completed is probable, though not for many years.

Useful Information.

The New Gas-Making Process.

We had not long since some notes on a new process of making coal gas which promised great things. We learn from Eastern exchanges that Prof. Adams, the inventor, lately gave a practical demonstration at his new works at Astoria, near New York city. He claimed, and experts present allowed the claim, that he, by his new process, makes seven feet of gas from a pound of coal, instead of four and a half feet, which is the maximum attainable by the old process. Second, that he extracts all the bituminous matter from the coal in the shape of gas, producing no tar and no ammoniacal liquid, and leaving as the only residuum coke of a better quality than that produced by the old process. Third, that the quality of the gas is much better than that of the old process, and fourth, that he can produce it just twice as fast.

The first point of difference between the old process and Prof. Adams' is that the retorts, instead of being complete in themselves, are made in pairs, with reciprocally acting connection by pipes. As the burning out of a retort takes four hours, the first retort is charged two hours before the second; and each one being charged as often thereafter as it becomes exhausted, it follows that one is always two hours ahead of the other. As, by the old process, the gas generated during the first and last part of the time occupied is inferior to that when the operation is in full blast, the pipes mentioned are so arranged that the product (gas, tar and ammoniacal liquid) of the retort that is producing the poorer gas is forced through the retort that is in full operation. Being thereby subjected to the influence of heat for the second time it is rendered into pure gas. This was at first doubted by some of those who examined the works, but an examination of the pipes from which tar and ammoniacal liquor would flow according to the old process (which pipes Prof. Adams has had made and placed in position) showed that not a drop of either was flowing.

This double distillation, while it effects a complete saving of the bituminous matter formerly used up in the tar, etc., is assisted by the filtering in of a small amount of petroleum and by the simultaneous decomposition of superheated steam, by which means the quality of the gas is improved. The final product is not a mixture of coal gas, petroleum gas and water gas, as might be supposed, but is a compound fixed gas of great purity.

Should the process be found to be practicable on a large scale—and Prof. Adams has manufactured many thousand feet already—the result will be a great saving to the gas companies and to the public, as gas can be produced for 40 cents a thousand feet, according to Prof. Adams' calculation.

To Color Gold Wares.

Our jewelry manufacturers will be interested in some notes on coloring gold of low grade of purity, as translated from German authorities for the *Jeweler and Silversmith:* Some colors have been prepared for producing a fine yellow color on 14 and 18 caret gold wares. Articles of less than six carets cannot be treated in this manner, but must be gilded. Coloring is only used in general for red gold, as yellow is mostly burnished. An excellent coloring for gold ware consists of 30 grammes of gold, 60 grammes of chemically pure saltpeter, 30 grammes of chemically pure salt, and 30 grammes of chemically pure hydrochloric acid. Several operations have to be performed, however, before coloring can be proceeded with. The red gold wares must be thoroughly burnished with tripoli, and must have a uniform dark surface and be boiled without having any specks. This is done by putting the article in boiling water containing borax, heating to a red heat in a clear coal fire, and then quickly cooling in water, afterwards letting it boil in dilute nitric acid (60 parts rain water with 2 parts of nitric acid) until the black coating has disappeared. The articles must not be touched with the hand, but a fine silver wire attached to them, and kept in water. Only earthenware must be used for the purpose of coloring. The crucible pot can also be employed. Two vessels must be placed right and left of the coloring matter with clean hot water for cleaning. A small piece of sal ammoniac is put in the coloring during its action, or even some urine. The color of the gold is far finer and more durable by this addition, which has been a secret to many. Karmarsch and Heeren give the following recipe in their "Technological Dictionary:" To one part of the gold take two parts by weight of common salt which has been dried over a fire, and four parts of saltpeter; they are rubbed well together and then boiled in an earthen vessel with a small quantity of water until the whole has become a dry powder. Then add three parts of spirits of salt (of the specific gravity of 1.165) and let boil until complete dissolution and a perceptible formation of chlorine gas. The objects are then immersed and kept quickly stirred, now and then raising them to see how the coloring is progressing. The process is generally completed in five or six minutes. The articles are then rinsed in hot water and then in cold water and finally in boiling water so that they may dry rapidly. Water must be only added to the color when unavoidable. Soldered places color at first black but afterward become yellow. The color cannot be made use of a second time, but may be kept and the gold recovered by aquafortis, filtration and precipitation through green vitriol. Herr Wagner recommends a solution of one gramme bromine, and 30 grammes of hromide potassium in 1,000 grammes of water as a gold color.

Inflammable Dress Goods.—Steam-Boiler Inspector Siebdrath, of Dresden, we learn from the *Polytechnic Review*, was lead by several distressing accidents that happened to female operatives in factories, from the catching fire of their dresses, to experiment to find a simple plan of rendering such dress goods uninflammable. He tried alum, but with little satisfaction, as the goods so treated burned afterward with more or less readiness. They were likewise injured in appearance. A 5% solution of phosphate of ammonia, however, gave very satisfactory results; the goods (linen and cotton) after treatment refusing to inflame—simply charring when brought in contact with flame. Treatment with a mixed solution of 5% alum and 5% phosphate of ammonia, gave equally satisfactory results. Even when gunpowder was rubbed into goods thus treated, they simply charred and the powder simply puffed. He suggests that female operatives exposed to danger from fire should have their working dresses impregnated and rendered uninflammable by the plan above described. The dress could be used a considerable time without requiring to be washed, and hence the cost of reimpregnation (about 50 cents) would not prove a serious item, especially when considered in connection with the immunity from danger that it carries with it.

Cement for Precious Stones.—The Turks glue diamonds and other jewels to their metal settings with a mixture made as follows: Dissolve five or six bits of gummastic, each the size of a large pea, in as much spirits of wine as will suffice to render it liquid. In another vessel dissolve in brandy as much isinglass, previously softened in water, as will make a two-ounce vial of strong glue, adding two small bits of gum ammoniac, which must be rubbed until dissolved. Then mix the whole with heat. Keep in a vial closely stopped. When it is to be used set the vial in boiling water. This cement perfectly resists moisture, and it is said to be able to unite effectively two surfaces of polished steel.

Coal.—Anthracite contains a small portion of volatile matter, its component parts being carbon, oxygen, hydrogen and nitrogen—the hydrogen being either combined with the oxygen to form water, or with a small portion of carbon to form carbureted hydrogen, which exists in a gaseous state in the pores of the coal. In bituminous coal, the hydrogen is combined with a larger proportion of oxygen and nitrogen, the mechanical difference being that the bituminous and free-burning coals, in particular, melt by heat when the bitumen reaches the boiling point—whereas authracite is not fusible, nor will it change its form until it is exposed to a much higher temperature.

Good Health.

Hints to Nervous Invalids.

Dr. Holbrook, in the *Herald of Health*, gives the following advice: Take plenty of sleep. Eight or nine hours each night will be better than less. But this is the chief difficulty; if you are nervous you cannot sleep; and a good night's sleep is both the cause and effect of coming recovery. When your sleep departs you are sick; when it returns you are well. So that hints to nervous invalids simply resolve themselves into rules for getting sleep. I give you mine, which has been burnt into me by a long experience.

1. Take not less than two hours of physical exercise each day, and in the open air if possible. Work of some kind is better than gymnastics, but swinging dumb-bells or Indian clubs is better than nothing. Useful labor I believe to be far the best, since the mind as well as the body has something to do with sleep and health. It is said that Lyman Beecher used to keep a pile of sand in his cellar and shovel it for exercise. Doubtless it was better than nothing; but for me let it be work, with hoe or spade, or ax or saw, or broom or flatiron, or washtub or kneading-trough, or something that does somebody some good. If you are too rich or too busy, or your time is too precious for you to do any of these things, or if you are so elegant, refined and fashionable that you are afraid of losing caste and soiling your white hands, then know that you are probably too refined and too lazy ever to have the best sleep and health. Excursions and travel may do you good, but never what some manual labor would do. God has made a law about "the sweat of the face," and no mortal can dodge it. The banker and the beggar, the queen and the maid-servant are alike subject to it.

2. Do not overwork the brain. Reading, writing, the hard study of books, and continued thought without any books, are all of them very healthful in moderation. But a little excess in any of these things will overtax your nerves and brain and drive away your sleep. Going to parties, making and receiving calls are all subject to the same law. If you see company and talk more than you ought to, you will not sleep.

3. Avoid all mental labor at night. If you are very feeble you may have to stop reading and writing, and stop seeing company and holding conversation as soon as the sun goes down—possibly before—and devote yourself to the sole business of keeping quiet. It may aid you to record in your diary the number of hours each day that you devote to manual and mental labor and to company, and the result of each day's work upon your health, until you have learned how much of each you can do without driving away your sleep.

4. When preparing to retire, warm your feet, with a hot bath if may be, and let your head cool. Warm your back, the naked skin; heat it between the shoulders—with a firebrand or some other way—as hot as you can endure it, but be careful not to heat the back of your head. If necessary, ask your physician for a counter-irritant, of croton oil or something, and rub it up and down the spine, especially between the shoulders, until it brings out an eruption. It will draw the blood from the head and greatly relieve you. A vigorous rubbing of the back by an attendant will help greatly. But do not let the attendant talk too much. Even the glare of the lamp drives away sleep. So put it out, and you will get drowsy sooner. The light of a great fire will be enough.

Narcotics and Stimulants.—Mr. Jez. Keelgrew, Commissioner of Agriculture in Tennessee, has published some interesting statistics as to consumption of narcotics and stimulants throughout the world. Paraguay tea, it is computed, is used by 10,000,000 human beings, cocoa by 60,000,000, chicory by 40,000,000, and coffee by 100,000,000. The consumers of betel are set down at 100,000,000, those of bashish at 300,000,000, and those of opium in one or another form at 400,000,000. These figures are, however, eclipsed by the proportions of the demand for Chinese tea, which is said to be used by half a billion; while the consumers of tobacco are not only still more widely distributed, but present the astonishing aggregate of 800,000,000. According to a careful estimate prepared for this report, tobacco is more generally used than any other single article of commerce consumed by man. The United States in 1860 produced more than 430,000,000 pounds of tobacco, but ten years afterwards the yield of the plantations had dwindled down to 260,000,000. The report does not state the exact quantity grown in any subsequent year; but it seems that the exports alone in 1875 reached about 220,000,000 pounds, valued at more than $25,000,000. According to the United States Bureau of Statistics, leaf tobacco valued at nearly $29,000,000 was sent out of the country in the year ending June 30, 1877. These figures would make tobacco rank sixth in the list of exported staples from the United States, cotton, breadstuffs, petroleum, and the precious metals alone exceeding in importance. In 1875 the best customers of the United States for tobacco was Germany, who, notwithstanding the large quantity grown in Prussia, took 56,000,000 pounds; while Great Britain, which produces none, took only 54,000,000 pounds.

Brain-Feeding.—The London *Lancet* is glad to find some small tokens that the need of "brain-feeding" is beginning to be recognized by the lay public. For example, it is at length perceived that to perform intellectual work thoroughly men must be supplied with fresh air. This scrap of wisdom has been excogitated in connection with the controversy about the ventilation of courts of justice. It is not unreasonable to anticipate that in process of time it may dawn on the consciousness of ordinary thinkers that just as muscle is fed and trained for physical exercise, so brain needs to be prepared and sustained in mind-work. The press of work and the strain of worry are so great in these days of hot haste and breathless enterprise that, except under conditions rarely established and maintained, the power of self-nourishment and repair in the mind-organ is not sufficiently strong to keep it in health. It follows that it must be fed and nourished by special design. An adequate supply of oxygen is the preliminary requirement. Then comes the question of food; and, whatever else may feed the brain, workers with this organ should be assured that alcohol will not sustain it. Alcoholism and oxygenation are directly antagonistic processes; and even if alcohol be food for the brain, the organ cannot feed when the nutrient fluid circulating in its vessels is disabled from the task of conveying oxygen, which happens whenever spirit is present in more than very moderate proportions in the blood. The relief afforded by alcohol from the sense of depression procured by a sack of oxygen, is, therefore illusory. It is produced by over stimulating an organ which is both exhausted and impaired.

The Black-Bottle Spider.—The Modesto *Herald* says that people would do well to guard against this poisonous insect. Several very sad cases have resulted from its venomous sting, and just now there are some patients undergoing treatment from that cause. Its bite, or sting, frequently results in paralysis, and one man we learn of had the left side of his body completely paralyzed from a bite on the shoulder. It may be recognized by a black, bottle-shaped body, average size, and long legs. We are informed that it will only be found where webs are permitted to remain without molestation, so it behooves all to see that their dwellings are rid of the unsightly spider web.

The Week.

The week has passed without noticeable events in the industrial world, nothing having transpired to greatly disturb the ordinary currents of business. The suspension of the Sierra Flume and Lumber Company by checking the manufacture of lumber and throwing out of employment nearly 1,000 workmen will prove a serious detriment to the local interests of the section of country where their operations were carried on. Creditors, however, will not suffer, as the company have ample means to satisfy their indebtedness, which does not exceed $200,000, while their assets are valued at $2,200,000; The Indian outbreak has continued to spread until it has come to assume vast and unexpected dimensions, indicating such a general dissatisfaction among the various tribes of Northwestern Idaho and Eastern Oregon as can only be quelled by a considerable force and very determined efforts. Already the whites have achieved several minor victories, and with the troops now in the field it seems probable that the war will be brought to a speedy end through the subjugation by arms or the voluntary submission of the disaffected savages. The troops, both volunteers and regulars, are entitled to much praise for their bravery and general good conduct evinced thus far. A vessel cleared at this port during the week for Callao, Peru, laden principally with mining machinery manufactured here for parties in that country. This, though not the first, is much the heaviest shipment of the kind yet made for South America, the consignment sent forward being only a portion of the entire amount contracted for, and the most of which is completed or in an advanced stage of construction. With the extension of mining and railroad enterprise in that country heavy supplies in this line will be required.

Vein Mining in California.

Taken as a whole, vein mining in California is in a fairly prosperous condition. In some districts the business is both thrifty and progressive, in others it is but moderately so, while in a few it is suffering from chronic stagnation or has been suspended altogether. In San Diego county, the most southerly section of the State where this industry has been pursued, it has failed to make the headway expected, the product of the mines, never very large, having remained about stationary for the past four or five years. Of the mines in this county, it may be said that while they have failed to enrich the owners and those investing in them, they have not, as has sometimes elsewhere happened, been a source of loss to those seeking to develop them.

In Los Angeles, the next county to the north, not much vein mining is or ever has been done. Recently a number of mineral lodes have been discovered in the Santa Ana mountains, in the southeasterly part of the county, leading to the organization of a mining district and some attempts at opening up the same. These ledges carry antimonial silver, with lead and in some instances also gold. So far as explored, they show signs of permanence and promise to remunerate a further investment of capital. A town named Silverado has been laid out in the district, which contains about 100 inhabitants, the most of them claim owners and workingmen.

In Inyo county mining languishes this summer. Results here have, in fact, thus far, caused general disappointment, admonishing all of the impolicy of allowing population, building and all manner of expenditure to get so far in advance of lode exploration and ore development. Of this region it can only be said that affairs having been at least restored to a normal condition, it may be expected that mining here will experience a more healthful growth, as the country possesses extensive mineral deposits, and has been pretty well outfitted with suitable reduction works. Among our lode mining counties Mono is just now one of the most active and prosperous. The large and profitable production made the past year by the Standard mine at Bodie, has served to revive prospecting in this section of the State, giving such an impetus to the business as threatens to bring in too many people and cause everything to be overdone. As yet, however, affairs there are maintained in a tolerably healthful condition, some new and seemingly important districts having been discovered, and many of the recent localities giving evidence of permanent value. While Alpine sustains its well earned reputation of being the county of great promise and little performance, it is due this laggard in the field of vein mining to say that several well conducted enterprises have lately been set on foot there. Albeit others after a long struggle have meantime succumbed and given up the ghost.

Along the gold belt, from Kern county to Tuolumne inclusive, a distance of over 200 miles, we find only here and there anything like a marked success in this department of mining to be noted. About Tailholt and Havilah, in Kern county, a number of small companies are making fair earnings. At Keruville, the big mill of the Jones-Burke company is running on ore of too low grade to afford much profit, and in this neighborhood, the Fryer Royal metal company have secured and are opening a property of standard value. In Mariposa, the Washington and Hite mines continue to do well, while in Tuolumne, the Soulsby, by its late success, has almost regained its ancient fame, there being various other properties in this county that are being worked with remunerative results. Still, so little along this entire stretch of country has been accomplished of an encouraging kind, that we would fain pass it by unnoticed, only that it possesses mineral resources of almost the first order, with great natural facilities for making them practically available.

Calaveras county can boast of several prosperous quartz mining enterprises, foremost among which is the Gwin mine, while in Amador, adjoining it on the north, this interest flourishes to an extent hardly equaled elsewhere in the State. The mines in this section are as a general thing looking and yielding well, and, while some of the mills, dependent upon water for their propulsive power, will be obliged to curtail or suspend operations before the season is over, a few having already done so, the yield of bullion will this year be larger than usual.

While neither El Dorado nor placer have yet distinguished themselves in this province of mining, both claim their ability to do so, and are really doing much towards making this claim good, the business already paying well in some localities and everywhere receiving much attention at the present time. Placerville, Georgetown, Greenwood, Colfax, Ophir and Auburn are here the most active neighborhoods of this industry. In Nevada county quartz mining has during the year made a new departure, an event due to a variety of causes, such as the really good character of many of the ledges, the facilities that exist for cheap mining, the advanced condition of the business and the large success that in many cases has attended its prosecution here. Then, too, the Fryer process, though it failed to achieve what was expected of it, by strongly directing the attention of capitalists towards this interest and really enlisting many of them in it, communicated to the business here an impulse that has carried it forward in a most remarkable manner. To here enumerate the many quartz enterprises now in full tide of success in this county, with others that have of late been auspiciously inaugurated, would require more space than can be spared: suffice it to say the foundation is being laid for a greatly increased gold production here, and that the annual yield from this source will be larger than for any preceding year.

Going north we enter a county where other branches of mining than the one we are considering are in the ascendant. But even here there are mining quartz properties that are making satisfactory returns for the labor and money expended upon them, and in some of which a very small, while in others a very large amount of capital has been invested. In Sierra county the Sierra Buttes and in Plumas, the Plumas Eureka companies continue to enjoy a prosperity extending back through a long series of years, and which there is good reason to suppose may reach into the indefinite future.

Placers on Upper Snake River.

A party writes to the *Idaho Statesman* from Salubria, on the Upper Weiser, inquiring about the chances for finding remunerative gold diggings on the head-waters of Snake river. In answer to this inquiry the editor of that journal replies that he is without definite information on that point, remarking that, however it might be as regards the upper waters of the Snake, there certainly are bars further down on that stream which will pay fair wages and which were worked steadily up to the time of the late Indian outbreak. Seeing like queries in different quarters indicating that there are others who would like information on this subject, we furnish herewith a few facts tending to throw some light upon it.

In the summer of 1870, at the time of the Snake river excitement, one of the editors of this paper made a journey to that region of country, and striking the river at the crossing of the Kelton and Boisie Basin road, followed the same to its source in the Wind River mountains, a distance of nearly 400 miles. As the gold dust found on the bars of the Snake was exceedingly fine, and the country traversed by that stream was mostly of a basaltic formation, and consequently without mineral veins, it was concluded that the gold had come from its upper confluents, which it might reasonably be expected would afford rich diggings. In this, however, we were disappointed, the gold dust, both as regarded fineness and quantity, remaining nearly the same along the river until we reached the foot of the mountains, when the current became so rapid that there was little chance for bars to form. At a great altitude in the Wind River range, the highest portion of the Rocky mountains, Snake river separates into two main branches, having many tributaries. These two branches, known respectively as the North and the South Fork, flow through beautiful grass valleys which, in the summer time, abound with all kinds of game. The bars along these streams all contain gold, but in such small quantities that they will not pay for working, the dust here being just as fine and difficult to save, as it is 300 or 400 miles further down.

After our party had been in the valley two or three days, and before we had time to sink on these bars, a large party of Sioux came in and notified us that we must desist from further searching after gold. They seemed to have no objection to our remaining there and fishing and hunting, but would not suffer us to do any more prospecting, a business we were the more willing to relinquish, as we had already about satisfied ourselves that it would not pay. We found places where a dollar or two per day could be made by sluicing, but this would be but a poor return, considering the shortness of the working season and the cost of getting to and living in this country, supposing the Indians would allow the whites to work there at all.

These valleys in the summer are full of buffalo, elk, bears and other kinds of game, which the Sioux come in large parties at that season to hunt, bringing with them their women and children, dogs, ponies and lodge fixtures. Camping here, they kill these animals in great numbers, and, curing their skins and flesh, pack them, on the approach of fall, down into the plains, where they spend their winters. These mountain valleys are to this people a perfect game preserve, and well knowing that the permanent presence of the whites would destroy it for this purpose, they will never willingly consent to have them there. Only in the summer could mines there be worked, and then these savages would be sure to put a stop to any attempt of that kind, assuming that the dirt was rich enough to pay.

It must be remembered that the Sioux inhabiting this section of country, though not particularly hostile to the whites, are brave and warlike, the men being large, muscular fellows, pretty well mounted and always well armed. They hold in great disdain the surrounding tribes and even show something of this feeling towards the superior race. When they came into the valley, they scarcely condescended to notice our party, riding directly over the camp of our party, as if we had been a squad of Chinamen. As Americans, we felt humiliated, but there was no hope for us. While itching to shoot the rascals, we had to turn it off as a good joke

Records of the Stetefeldt Furnace.—No. 1.

The construction of the Stetefeldt furnace has already appeared in the PRESS, and its method of working is too well understood to require comment. We simply wish to add through our pages the following contribution to technology, for which we are indebted to the inventor himself, Mr. Stetefeldt. We publish these extracts, as far as possible, unchanged from the manuscript which he has prepared for publication in a separate form. The analytical work mentioned was undertaken in the laboratory of State Chemists, Falknean and Reese, and may be relied on as correct. The same may be said of the rest of the matter, which is more than can be usually said even of what are claimed as the reports of disinterested parties.

Improvements in the Furnace Itself.

These consist in slight but important changes in the charging and discharging apparatus. The latter is now effected by making the bottom of the furnace a movable iron damper which rests on brackets with friction rollers. By simply withdrawing this the ore is discharged into a car standing upon a railway beneath. The feeding machine consists of a cast-iron frame, which is placed on top of the shaft, and is provided with a damper, which is drawn when the furnace is in operation, but is closed when, for any cause, the furnace stops for any length of time, or when the screens have to be replaced. This frame contains a cast-iron grate, to the top of which a punched screen is fastened. This latter is made of Russian sheet iron, or of cast-steel plate, with holes one-tenth to one-eighth inch in diameter. Above the punched screen is placed a frame to the bottom of which is fastened a coarse wire screen, generally No. 3, made of extra heavy iron wire. This latter frame rests upon friction rollers. The brackets which hold these friction rollers can be raised or lowered by set screws, so that the wire screen may be brought most to or removed away from the punched screen, as may be desired. By means of a shaft with eccentric the wire screen can be put into a sharp oscillating motion. Above this screen and fastened to movable brackets, extend arms which come nearly in contact with the wire screen. The distance from it can be adjusted by set screws. By means of conical pulleys, the wire screen can be put in motion at the rate of 20 to 60 strokes per minute, just as may be desired. By this means the amount of ore discharged into the furnace may be exactly regulated. This can also be done to some extent by varying the distance between the two screens and that between the wire screens and the blades. The effect of these blades is to keep the pulp in position when the screen is oscillated and to act as distributers of the pulp over the whole surface of the screen. Above the screens is placed the ore hopper. The hopper receives the ore from an elevator which receives its supply from another hopper, into which the fine ore is discharged by the crushing machinery. The ore is generally pulverized through a No. 40 screen. It will be seen that this arrangement enables the charging to be done without any large and heavy building upon the top of the furnace, while the fireman standing below can have perfect control of the feeding machinery.

Critical Remarks Upon the Furnace.

It is evident from the above description that the working of this furnace can be regulated in the most perfect manner, and that no disturbance can occur which does not admit of an immediate and easy correction. Even before it had reached its present perfection, Dr. R. W. Raymond, U. S. Commissioner of Mining Statistics, speaks of it in his report of 1870: "This invention is one of the most important steps of progress yet achieved in our American silver metallurgy."

The Stetefeldt furnace can be used for oxidizing as well as for chloridizing roasting, but it is mainly for the chloridizing roasting of silver ores that it has been generally introduced.

Mr. Guido Kuestel thus describes in his treatise on the "Roasting of Gold and Silver Ores" the chemical changes which take place in the Stetefeldt furnace in the chloridizing roasting of silver ores:

"Considering the old, or rather the usual theory, deduced from the roasting process in the common reverberatory furnaces, that sulphates must be formed before the salts can be decomposed, and not till then will the chlorination begin, it would seem that for these chemical reactions, more time is required than a few seconds, but this is not the case. As soon as the ore and salt enter the furnace, each sulphuret particle ignites in the glowing atmosphere, evolving at the same time sulphur, which, in the presence of the atmospheric air, is turned into sulphurous acid, and the metal into an oxide, or in part directly into a chloride. The sulphurous acid in contact with the ore particles and oxygen becomes sulphuric acid. The temperature is nearly too high from the start to form sulphates, so that the sulphuric action turns its force on the red-hot salt particles, setting the chlorine free. All these unctions are performed instantaneously. The whole space in the furnace is filled with glowing gases of chlorine, hydrochloric acid, sulphurous acid, sulphuric acid, oxygen, steam, volatile base metal chlorides, etc., all of them acting, decomposing and composing on the sulphurets with

great vigor. The chlorine acts on the sulphurets directly, forming chlorides of the metals and chloride of sulphur; it attacks, decomposingly also, oxides and sulphates, if present. The hydrochloric acid performs the same office. Also, metallic silver if it should occur in the ore would be converted into chloride. The sulphuric acid, besides decomposing the salt oxidizes the sulphurets directly, etc.

"Considering now an ore particle in a red-hot condition attacked simultaneously by all these gases while falling, the final chloridizing result is inevitable. The finer the ore particles are, the more perfect the chlorination; but even if some coarser parts (to a certain degree) should reach the bottom not thoroughly chloridized, this would be finished in the pile, as the chlorination and evolution of chlorine gas continues in the red-hot accumulation at the bottom of the furnace."

Of the other purposes to which the furnace is adapted, the following may be mentioned, viz.

(1.) The oxidizing roasting of gold-bearing sulphurets, preparatory to the extraction of gold by Plattner's process or by amalgamation.

(2.) The oxidizing or chloridizing roasting copper sulphuret ores, preparatory to one of the leaching operations.

(3.) The oxidizing roasting and clagging of galena ores, preparatory to their reduction in the blast furnace. By proper changes in construction, the furnace could be easily adapted to this purpose.

Cost of Construction.

Considering the enormous capacity of the Stetefeldt furnace, and its durability, if well constructed, it is by far the cheapest furnace with regard to original cost of erection.

The largest sized furnace, capable of roasting from 50 to 70 tons of ordinary ores and from 30 to 35 tons of very base sulphuret ores in 24 hours, requires the following amount of materials, from which the cost of construction in any particular locality can be easily calculated by any architect or mill-wright, viz.:

Fire-bricks for fire-boxes and arches exposed to flame	1,500
Common bricks of good quality for furnace, large system of dust-chambers, chimney and cooling floor	200,000
Bolts and nuts for anchoring furnace and dust-chambers	2,500 lbs.
Wrought-iron braces, flat iron for car-guides, tools, etc.	4,500 lbs.
In castings	10,000 lbs.

All the castings are very plain and simple, the water jacket on top of the furnace and water damper having been discarded. Considerable work is required only on the feeding machine, feeding machine damper, discharge damper, and some of the fire doors, which will be covered by an additional charge of about $700 added to the price of ordinary plain castings. The cost of these iron discharge cars is $125. For a furnace of 15 to 20 tons capacity without hopper discharge and extensive dust chambers, the amount of materials may be estimated at two-thirds of the figures given above.

We will give an example of the cost of erecting a Stetefeldt furnace of largest size at stated prices for materials, freight and labor.

1,500 fire bricks at $60 per M	$ 90 00
200,000 common bricks at $15 per M, delivered	3,000 00
7,000 lbs. wrought iron in bolts, braces, etc., at 8c	560 00
16,000 lbs. castings at 0c.	960 00
Labor on castings	700 00
Iron discharge cars	125 00
Freight on 12,000 lbs. fire brick and 23,000 lbs. iron, at 2c.	700 00
225 days mason labor at $6	1,350 00
180 days mason's helper labor at $3	540 00
To grading, foundation, sand, scaffolding, etc.	600 00
Superintendence of construction	400 00
Total	9,025 00

This estimate does not include cost of conveyors and elevators, and the building to cover the furnace. A part of this expense belongs in reality to the pulverizing machinery. These items will vary materially according to the price of lumber. From $3,000 to $4,000 is a liberal estimate for most mining districts.

Expense of Roasting.

The expense of roasting in the Stetefeldt furnace can be calculated as follows:

Fuel.—The amount of fuel required in 24 hours is from two to four cords of good wood (or its equivalent in coal), according to the capacity of the furnace and character of the ore. Furnaces of 20 to 25 tons capacity have generally consumed from two and one-half to two and three-quarters cords of nut-pine. Only well-seasoned wood should be used for firing the furnace.

Labor.—Two firemen take charge of the furnace in 24 hours. They work in 12-hour shifts. For discharging and cooling the roasted ore, the number of men is in proportion to the amount of ore roasted. For instance a furnace of 25 tons capacity requires four men in 24 hours to discharge and cool the pulp and get it ready for amalgamation.

Salt.—For chloridizing roasting of silver ores the Stetefeldt furnace requires less salt than any other furnace, because the decomposition of the salt is very perfect and the chlorine and chloridizing gases emanating from the roasted ore at the bottom of the shaft act upon the falling ore which floats in an atmosphere of these gases. Ores which are free from lime and magnesia can be chloridized in the furnace with a minimum of salt.

During a run of nine months at Surprise Valley mill, Panamint, Cal., where an average chloridation of 92% to 93% was obtained in the roasting of silver ores, assaying $75 per ton, only 2½% to 3% of salt was used. In fact a still lower percentage of salt would have sufficed had the saving of it been any object. In cases where the ore carries lime and magnesia or a large percentage of base sulphurets, it is of course impossible, even in a Stetefeldt furnace, to obtain good chloridation with such a slight per cent. of salt, and generally from 5 % to 8 % are required. The salt is either mixed with the ore at the dry kiln and crushed with it, or they are crushed separately and mixed by proper machinery before entering the furnace.

We give an example of cost of roasting in a Stetefeldt furnace of 25 tons capacity in 24 hours, at stated prices for labor, fuel and salt, such as are generally paid in mining districts in Nevada:

2 firemen at $4.50	$ 9 00
4 ore coolers at $4	16.00
2½ cords wood at $8	22.00
Wear and tear of screens, etc.	1 00
Labor and fuel for 25 tons	$48.00
Labor and fuel p r ton	1.92
7% salt at $40 per ton	2 80
Expense of chloridizing roasting per ton	$ 4 72

Chloridation of Silver Ores.

The percentage of silver chloridized in roasting silver ores in the Stetefeldt furnace varies according to the character of the ore and the care with which the furnace is managed. Results as high as 97% have been obtained, while the average chloridation generally range from 87% to 93%. Ores free from sulphur or with only a slight percentage of it, should be mixed with 1% or 2% of iron pyrites, otherwise decomposition of the salt is not possible. Oxidized ores, however, containing peroxide of manganese, or iron which gives off oxygen when heated, can be successfully chloridized by themselves. The best results are obtained by mixing oxidized ores with sulphuret ores, particularly in the presence of peroxide of manganese. In such cases the capacity of the furnace is much increased. The presence of copper is very favorable to the chloridation of silver, and if the ore is of such a nature that it bears a high heat without sintering, the chloride of copper formed in the upper part of the shaft can be almost completely decomposed and very fine bullion produced by amalgamation. As an example we state the result of an experiment made at Surprise Valley mill, Panamint, Cal. The ore roasted at a low temperature gave bullion only 300 to 400 fine by amalgamation, the base metal being copper. By roasting the same ore at a high temperature the bullion produced was almost free from copper, its average fineness being 980 during a run of nine months.

All antimonial ores are chloridized with great facility, and with a good system of duct chambers the loss of silver is almost imperceptible. The same is the case with zinchlende. Silver ores containing galena are treated by the Stetefeldt furnace with good results. The lead, however, has a tendency to produce lower chloridations. Guido Kustel says in this regard: "The baking of the ore during chloridation in the presence of lead cannot take place in the Stetefeldt furnace; and it is therefore very probable that a higher amount of lead will be less injurious than in any other roasting process." This has been fully verified by practical experience.

Advantages of the Furnace.

The Stetefeldt furnace recommends itself not only by its durability, by its economy in fuel, labor and salt, but by the ease with which ordinary laborers can learn in a very short time to control its workings. This has been fully verified wherever it has been introduced, frequently under the most unfavorable circumstances.

Patents.

The claims of the Stetefeldt furnace patents cover original inventions which have been fully sustained in the courts of the United States. The most important of the letters-patent of which the Stetefeldt Furnace Company is the assignee, are as follows, viz:

1. Letters-patent No. 100,237, dated March 1st, 1870. Improved machine for feeding ores into shaft-roasting furnaces.

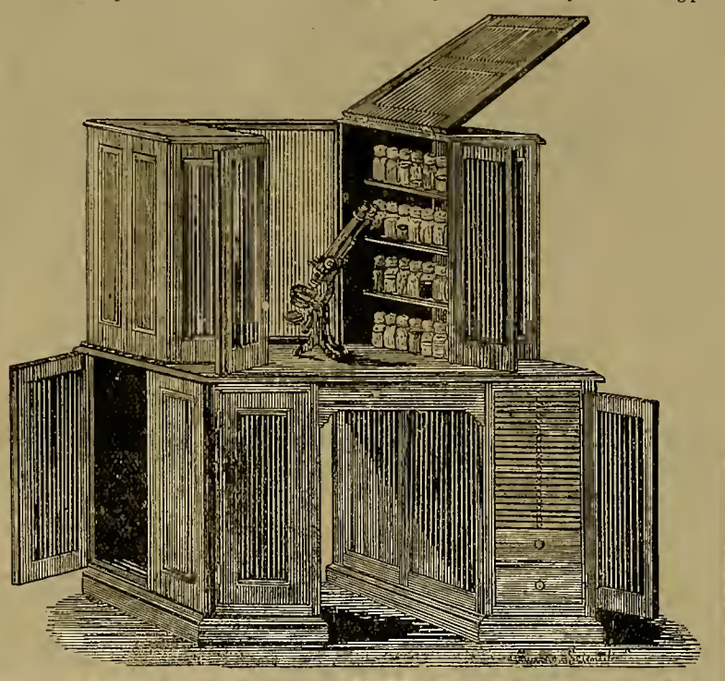
2. Letters-patent, re-issue, No. 3,808, dated January 25th, 1870. Improved process for treating silver ores.

3. Letters-patent, re-issue, No, 8,266, dated May 28th, 1878. Improvement in furnaces for roasting and treating ores.

All these patents have been granted to C. A. Stetefeldt. In addition to these the Stetefeldt Furnace Company has secured the exclusive right to use, for chloridizing purposes, every furnace patented in this country prior to the Stetefeldt patents, with which there could be even a trivial or fanciful interference.

In our next issue we will give an account of some of these furnaces which have been erected, with the results obtained with them.

THE directors of the Atchison railroad expect to push the road as far as Santa Fe, New Mexico, in 1879.



DR. MOUSER'S CABINET FOR MICROSCOPE, ACCESSORIES AND MATERIAL.

Dr. Mouser's Cabinet for Microscopic Work.

Our engraving on this page shows a cabinet, designed by Dr. S. M. Mouser, of San Francisco, one of our leading microscopists and member of the San Francisco Microscopical Society. This cabinet he has had constructed in the best style of the cabinet-makers' art, and, in addition to its high value as a working apparatus, it is a handsome piece of furniture, which well accords with the other appointments of his elegant office. We are prompted to present the engraving and the following description, so that other microscopists may be benefited by the enterprise which Dr. Mouser has carried out for himself. Dr. Mouser furnishes us the following notes descriptive of his cabinet:

Having long felt the inconvenience of working on an open table, where everything was exposed to dust and intruders, I planned this cabinet, which I find a most convenient piece of furniture.

The whole cabinet is 46 inches in length. The lower part is 28 inches in depth, from front to rear, and 28 inches high, with open space in the center—running entirely through from front to rear—20 inches wide and 24 inches high, admitting the feet and knees as the operator sits at his work. On each side of this open space is a door, 10 by 22 inches, inclosing a tier of 26 trays, containing 24 slides each, and two drawers, three inches deep each.

Behind these trays and drawers is a space large enough to contain case for microscope, which is accessible by a door opening at the end of cabinet.

Above the open center is a drawer, the full width of it, two inches deep, and running through from front to rear.

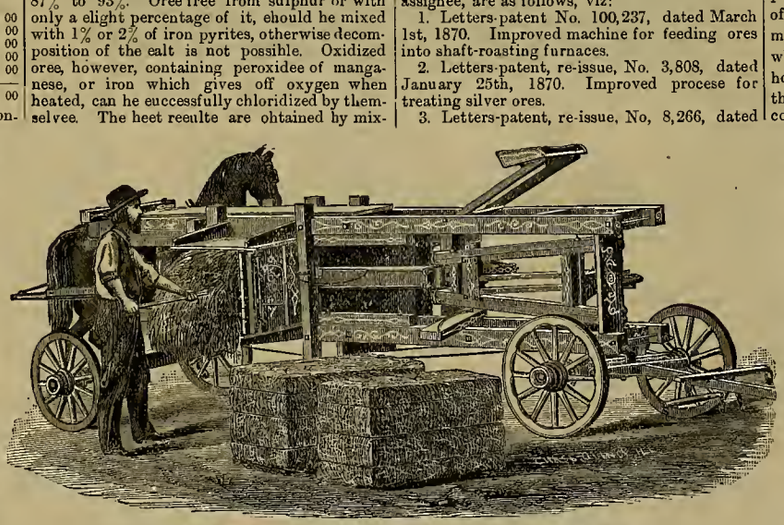
The upper part of the cabinet is the same length of the lower, but only 22 inches from front to rear, and 24 inches high, leaving a ledge six inches wide in front. This upper part also has open space in the center, 22 inches wide, the back part of which is enclosed with plate-glass to admit light, while the front has two panel doors and the top one, which is hinged to one side, allowing the center space to be closed in a moment. In this center space stands the microscope, always ready for use, with whatever material is being manipulated, and can be closed up in an instant and protected from dust and intruders.

On the left hand side of this open space are fourteen drawers in two tiers, three inches deep, and ten inches from front to rear and drawing into the open space. On the opposite side are three shelves, for the numerous bottles necessary for microscopic work.

The whole cabinet is fine panel work of black walnut, finished back as well as front, highly polished, and is a handsome piece of furniture. It is on castors, and can be rolled to any part of the room desired, always placing it with back to a window for light. Everything necessary for microscopic work can be kept in it, and the operator can reach all as he sits at his work.

The Ertel Portable Press.

We present on this page an illustration of a portable hay press, invented by Mr. Geo. Ertel, of Quincy, Ill., who has for ten years been manufacturing the Ertel Beater Hay Press, which has a wide reputation. The public, however, demanded a press of less cost, one that could be operated with less force, that could be used in the field and moved from stack to stack without loss of time. The press can be hauled about by any common wagon team of two horses, and passes through gates where a common farm wagon can pass, and when drawn to a stack, is ready for work. Ten tons of hay pressed by it can be loaded in an ordinary box car. The size of the bales in the press is 18, 24 and 34 inches. They are very smooth and square, and will weigh from 200 to 250 pounds each. Sixty of these bales can be made in a day, and from 100 to 115 of the same can be loaded in almost any ordinary box car. The weight of the complete press, with axles, wheels, tongue, double-tree, tie-making machine, etc., is 3,200 pounds.



THE ERTEL PORTABLE ONE-HORSE HAY PRESS.

This press is worked in a horizontal position, resting on four wheels. The sweep or power is on the side of the press, whereby the levers are drawn in with a chain seven feet in length, which is fastened directly from the levers to the power, and is then worked without the aid of a sheave or pulley, whereby all friction is avoided, being operated in this way:

One horse is hitched to the end of the sweep, and when going to the right, opens the press or levers; then the charge of hay is placed in the press by a door which locks itself as it is shut; while this is done the horse is moving round, pulling to the left, which motion closes the levers or press, bringing the pressure to bear; this operation also opens the feeding door without any further attention. As soon as the horse has reached the extreme end going to the left, he turns around, going the other way again to open the press, and the movement is so repeated until the bale is filled and pressed; then the doors are opened and the three hoops or ties put on; when the horse is started again, which motion runs the follower back, and as the bale is now free it can easily be removed.

FOREIGN PATENTS.

MINING AND SCIENTIFIC PRESS PATENT AGENCY, SAN FRANCISCO, CAL.

In offering the following circular and price list for foreign patents, to our clients both past and future, we have been careful to give the information contained in it in such a condensed form that the inventor can see at a glance the principal facts which he is desirous to know concerning each country, and without the confusion which more detail would add.

When the inventor has fully decided to apply for patents in certain of these countries, we are always ready to give any further information that may be needed.

Our practice has always been to prepare all the papers for patent applications in English speaking countries, so that the inventor may sign them and take out his patent in his own name.

We have skilful and reliable agents in every principal country in the world, and with the experience of the past and our present knowledge, we feel sure that we can give satisfaction to all who are willing to pay a fair price for thoroughly good, conscientious work.

Our rates have been reduced somewhat, and will, we think, be found more favorable in the aggregate than those of any other house.

The importance of obtaining patents in foreign countries, is obvious to all American inventors; but owing to the expense formerly attending these applications, and also to a lack of information on the part of inventors, as to the requirements in introducing and working their inventions, not as much use has been made of the patent privileges of these countries as might have been expected under other circumstances.

The patent laws of many countries, and notably Germany, have been very much improved of late years, and the rights of inventors are much better protected, now as the advantages which a country derives from inventions are better understood and appreciated.

The immense agricultural and manufacturing interests of many of these countries makes the introduction of improved machines and methods of greater importance, and renders the return to the enterprising patentee more certain and remunerative.

In France, Belgium, Austria, Germany, and some other European states, the patent becomes void upon the expiration or lapse of a patent of prior date, obtained in another country; and as in some of these states the specifications are published immediately after application, it is best to take out patents in all the countries in which it is desired to protect the invention, simultaneously.

In France and some other countries, medicines, articles of food, pharmaceutical compounds, and some other inventions are not patentable, although the processes may be; and in some countries warlike inventions are not patented, but are often appropriated by the government upon their own terms.

In England, France, Belgium and Spain, patents are usually granted if in their proper form, while in Germany, Austria, Russia, Sweden and Denmark, an examination is made, and all claims not considered novel are refused.

Germany especially, however, protects her patents, and punishes infringement as a criminal as well as a civil offense. In most of the countries, except England and the colonies, the patent must be worked in the country, and the working officially proved to the government within a certain time, or the patent will be forfeited; but, except in Austria, we can have the patent properly worked for a comparatively small sum of money. The Austrian law, however, requires the machinery to be manufactured in that country. In any case, however, if the patent be sold or disposed of, this difficulty is avoided by the inventor.

Australian Colonies.

See our special circular giving full information for these colonies.

Austria.

The term of an Austrian patent is limited to fifteen years, but the patent may be taken for a shorter period, and prolonged if desired. The invention must be worked in the empire within a year from the date of the patent, and becomes void upon the expiration of a patent of prior date obtained in any other country.

The cost of an Austrian patent, with all expenses paid for the first year, is $100. A small yearly payment must be made to prevent the patent from becoming void.

Belgium.

Patents are obtainable in Belgium for twenty years, but if patented abroad, the patent will expire at the same time with the original patent. The patent must be worked within a year of the time of its being worked abroad. A government tax is payable each year, beginning with ten francs and increasing ten francs each year.

The expense of obtaining a Belgian patent is $90.

Brazil.

Imperial diplomas, possessing the legal force of patents, are granted for terms of from five to twenty years to inventors or importers of inventions. No tax is demanded by government, but the inventions must be worked within two years.

The expense of a Brazilian patent is $300.

Canada.

The patent law of Canada is modeled after, and similar to that of, the United States. Patents are granted in Canada for terms of five, ten or fifteen years, the shorter terms being extensible. A model is required for this province; also a petition and duplicate set of papers of special sizes. The invention must be worked in the province within two years after the date of the patent. The Canadian patent extends to all the provinces north of the United States, known as British America, and must be applied for within twelve months of the date of an American or foreign patent.

The cost of a Canadian patent, including express charges on model, etc., is $65, and upwards.

Denmark.

The terms of a Danish patent varies from three to twenty years, being fixed by government. Patents of importation do not usually exceed five years. The invention should be worked within one year.

The expense of a Danish patent is $100.

East Indies.

An East Indian patent is granted for a term of fourteen years, and must be for a new invention of public utility. The applicant must be the inventor, his executor, administrator, or assignee, and may be a resident, non-resident, British subject, or alien. The papers necessary are a petition, declaration, specifications and drawings, together with five copies, one for each of the Presidencies. The time of working the patent is not limited.

The cost of an East Indian patent is $300.

France.

The term of a French patent is fifteen years, but is limited by the duration of a prior patent in a foreign country. The invention must be worked within two years of the date of the patent. A payment of 100 francs ($20) must be made each year, or the patent becomes void. No model is required. The papers necessary are a petition, specification and drawings, in duplicate.

The cost of a French patent is $100.

German Empire.

Under the law of June, 1877, patents may now be taken out for the entire German Empire. The duration of the patent is fifteen years. A valid German patent cannot be obtained if the specification has been published in any way before the German application is made. It should therefore be made before the issue of the American or English patent. The patent must be worked within three years of the grant. Models are only required in special cases, as in fire-arms. Specifications and drawings must be furnished in duplicate and of special sizes. An annual tax is payable, beginning with £3 the second year and increasing by £2 10s. each year.

The expense of a German patent is $100.

Great Britain.

A British patent includes England, Ireland, Scotland, Wales, the Isle of Man and the Channel islands, but no colonies, as these have their own patent laws. The duration of a British patent is fourteen year; but in order to prevent it from expiring, a tax of £50 must be paid at the end of three years and £100 at the end of seven years. It is not imperative that the patent should be worked within a given time, but it is, of course, for the interest of the patentee to introduce his invention. A model may be deposited in the Patent Office museum, if desired, and will often assist in introducing the invention. The patent is granted to the one who first introduces it, and will not be sustained by the courts if it was publicly known in Great Britain before the date of the patent. No examination is made as to the novelty of any invention for which a patent is asked.

There are two methods of taking out a patent. The first is by filing a provisional specification, as it is called, and then filing a final or complete specification within six months afterwards. In the second, the complete specification is filed with the petition, and the patent is completed at once.

The disadvantages of filing a provisional specification are, the short time which elapses before the final specification must be filed, to prevent losing the patent; and the fact that whoever files the complete specification and obtains the great seal first, will hold the patent, even if another has a provisional specification on file, besides the chance of mistakes in completing the final specification. The patent may be taken out in the name of the foreign agent and afterwards assigned to the inventor, which is the usual practice, or the papers may be completed so as to be signed by the inventor himself, and the patent be taken out in his own name. The latter is our method. The documents necessary are a petition, declaration, specification, on parchment, and drawings in duplicate. No model is required, but the drawings should be very explicit. The expenses of a British patent is $250.

Italy.

The patent may be taken out in this country from one to fifteen years. If taken out for a shorter period, the patent may be extended by the payment of a tax of about £1 16s. for each extension. Patents for less than five years should be worked within one year. Those over five years, within two years; but the time may be extended upon a proper showing. A tax of £3 is payable the second year, increasing by £1 every third year. The documents required are a petition, specification and drawings in triplicate.

The expense of an Italian patent for six years is $200.

Norway.

A Norwegian patent is granted for from five to ten years, the duration being fixed by government. The invention should be worked within two years from the date of the patent. No annuities are demanded. The documents required are a petition, specification, and drawings in duplicate.

The cost of a Norwegian patent is $175.

Portugal.

The terms of a Portuguese patent is fifteen years. A tax of £2 is payable annually. The government reserves the right to appropriate inventions of public utility, an indemnity being paid to the owner.

The cost of a Portuguese patent is $300.

Russia.

Russian patents are granted for three, five and ten years; no extension of the terms for which it was originally issued being allowed. Inventions may be patented in the empire if not publicly worked previously, whether patented elsewhere or not. The patentee may be the inventor, his assignee, either a native or a foreigner. An examination made, as to novelty, correctness, etc., and patents are sometimes refused. The patent should be worked within one-fourth the time for which the patent is granted, and proof of the practical workings should be deposited with the Ministry within six months after such working. The importation of the patented article does not affect the validity of the patent.

The cost of a Russian patent for five years is $300; for ten years, $600.

Sweden.

The duration of a Swedish patent is usually ten years, and the invention must be worked within two years. There is an examination as to novelty. No model is necessary. The documents required are a petition, specification and drawings.

The expense of a Swedish patent is $175.

Spain.

The duration of a Spanish patent is fifteen years, but the patent may be taken for five years and renewed. It must be worked within a year from the date of the patent. No strict examination is made; no model required. The documents necessary are a petition, specification and drawings.

The cost of a Spanish patent for five years is $250.

Other Countries.

The following countries are of lesser value to patentees in general than those before mentioned; but in some cases patents may be advantageously taken for these countries also:

COUNTRY.	ALL PAID FOR.	PRICE.	EXTENSIBLE TO.
Antigua	7 years	$250	14 years
Barbadoes	14 "	260	.....
Bolivia	20 "	275	30 "
British Guiana, and Demarara	7 "	275	21 "
Ceylon	14 "	300	28 "
Cape of Good Hope	3 "	200	14 "
Chili	10 "	300	20 "
Cuba Porto Rico and Philippines	5 "	300	10 "
Dominica	14 "	250	.....

Our general circular of hints and information for inventors and patentees will be sent to any address on receipt of postage stamp. Also our special circular for the Australian Colonies and India.

DEWEY & CO.,

UNITED STATES AND FOREIGN PATENT SOLICITORS.
OFFICE OF THE "MINING AND SCIENTIFIC PRESS" AND "PACIFIC RURAL PRESS," SAN FRANCISCO, 1878.

From A. Patentee.

SAN FRANCISCO, July 1st, 1878.

MESSRS. DEWEY & CO., PATENT SOLICITORS.—*Gentlemen:*—On the first of June I made application for Letters Patent for an improvement on a fire-resisting and non-conducting compound through your Patent Agency, and was agreeably surprised to receive official notice that the patent had been allowed on the 15th day of June, in the unprecedented short time of fifteen days from the time it left here.

This is the seventh patent which I have procured through your Agency, entire satisfaction being given in each case, and I shall take great pleasure in recommending your firm for reliability and promptness to all inventors with whom I may come in contact.

I have now two more cases ready, and shall make the application through your Agency.

Yours Truly, GEO. R. EVANS.

Another Compliment.

LOS ANGELES, May 21st, 1877.

MESSRS. DEWEY & CO., Patent Agents, S. F.—*Gentlemen:*—I have just received my letters patent on machine for opening oyster shells, and compliment you upon your success. I shall not only contribute to you my own business, but also that of friends. Thanking you, gentlemen, for your promptness and the very thorough manner in which you have prosecuted this matter, I am, yours truly. T. W. TEMPLE.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore over formed by nature.

The cost of Roasting and Chloridizing is as follows:

One man, per day	$3 50
One man, per day	3 00
Wood, 1½ cords at $3	7 00
Cost of 20 tons	$13 50
Cost of one ton	67½

From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Novada and Idaho.

Any persons wishing any reference can address:

Judge Wm. Webster, Paymaster Mine, Reno, Nev.
Lewis Chalmers, Manager Exchequer and IXL Mines, Silver Mountain, Cal.
J. S. Cone, Vice-President Tehama County Bank, Red Bluff, Cal.
R. H. Campbell, Superintendent Afterthought Mine, Redding, Shasta County, Cal.

For further information, apply to

D. J. O'HARRA, Reno, Nevada.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco.

J. HEPBURN,

Mechanical Draftsman and Engineer

No. 214 Sansome Street, (Room 29,) S. F.

Working Drawings Furnished. ☞Premium obtained for Designs furnished the city for proposed Steam Fire Launch.

Note.—We desire to call special attention to the organization of our Grammar Department, separate from the Academical, and solicit the patronage of parents and guardians of small boys

LAND! BOUNTY!! PENSIONS!!! PATENTS!

Do you want to buy, sell or exchange lands or other property in any part of the U. S. or Canadas? Are you a Soldier or Sailor, in want of a Patent? Why not obtain more Bounty or Pension? Do you want to locate Government or State Lands without settlement? Why not? When I have the well-known Approved Soldiers Additional Homesteads, under seal of the General Land Office, and that can be located without settlement, upon any Government $1.25 or $2.50 lands, subject to homestead. The Sioux Half-Breed Scrip, for location upon unsurveyed lands.

Land Warrants and Scrip of all Kinds

For cash, or part on time. Good title given or no pay. Have you any lands with an imperfect title to sell, or choice vacant lands you know of which could be located to advantage; or claims not lawfully held, which we could contest. Let me hear from you in full, and I will do my best to inform you what is to your advantage.

I will mail you a circular explaining all, and a copy of the new Pension Law. Address, (plainly)

D. H. TALBOT,
General Land, Scrip and Warrant Broker, Sioux City, Ia.

Smelter and Refiner.

A competent person is desirous of receiving the position of Superintendent of a Smelting and Refining Works. Can give satisfactory reference for ability to smelt all lead ores, refine silver and make market lead. No objections to go to the Territories. Address P. F. M., this office.

SWEET Chewing JACKSON'S BEST NAVY Tobacco

Training Schools.

President Elliot, of Harvard University, has well said that "the welfare of the universities dopends upon the welfare of the training schools." Our State cannot yet hoast of a stalwart university. Oue manifest reason is that the schools which furnish the students for the University either do not take time enough to do their important work well or clso lack the qualifications to accomplish what they attempt.

Tho signs of the times indicate that these foundation defects in the higher education will soon be eliminated. Foremost among the agencios quictly at work solving this all-important problem ie, as it occurs to us, the Golden Gate Academy at Oakland.

This institution has just completed the seventh year of its history. Its years and its work entitle it to rank among the permanent educational forces of tho Stato. The first class of pupils prepared within its walls has just graduated from the State University of California. Next year, Yale, Amherst and Dartmouth will graduate others of its students. It claims to do foundation work in education according to most approved etandards. With equal diligence it aims to expand the character into the highest type of nohle manhood. Recognizing also the paramount importance of a sound body in order both to the highest mental development and to the best fruite of such culture in life, it has provided a woll-equipped gymnasium for daily exercise and a hrief military drill, to emphasize the method and system which ehould characterizo the true student. Its instructors are educators by profession. Its huilding is a model of comfort, convenience and architectura elegance. The founders and guardians of this academy are many of them graduates of the famous Phillips' Academy, of Andover, Mass. which has recently so worthily celebrated its centennial. It is tbeir purpose to make the Golden Gate Academy like unto this "fore most of Eastern training schools." May the completion of its centenary he as greatly honored.—*Argonaut.*

Frisco.—The Frisco reduction works etarted up with their new hoiler on the 11th ult., and up to the 28th, with some interruption, and turned out eigbt bars of silver, valued at $9,030. They are working from 10 to 15 tons of ore every 24 houre. The machinery ie working well now. The chloridizing furnaces will be completed next week, and, from the presen indications, the pioneer leachers of Utah, Messrs. Harries & Tischer, will make a success of their works bere. The Frisco emelter ba been continually running on Bonanza ore, turning out over a car-load every 24 hours, and having quite a lot of bullion on the dump. Th C. C. company's smelter bad been running up to yesterday, and has shut down for repairs and over the Fourth of July. They have als bullion on their dump. The Cave mine, owne by Godhe & Co., is looking well, and they ar boisting and shipping ore daily to the Frisc smelter. The Hedges, adjoining the Cav mine, we are informed, is to he purchased an worked by a party of capitalists. The Bonanz continues to look well and the working shaf bas been connected with some of the lowe works. They are shipping ore daily to th Frisco and company's smelter and the leachin works.—*Salt Lake Tribune.*

Buffalo Horn, the present leader of th Bannocks, ie well known in this city an throughout all the region of country embrace between the Sierra Nevadas on the west, th Missouri river on the east, the Pacific railroa on the south and the Dominion of Canada o the north. He is a balf-breed, and bas alway been friendly to the whites. Two years ag during the Black Hills campaign, be w Crook's chief scout, and in that position ou ranked even such men as Wild Bill and Ca tain Jack Crawford. He is thoroughly fami iar with the strategetical tactics of the Unite States troops, hrave to rashness, and hardy b yond even the usual run of Indians. He wi probahly not lay down his arms until absolute driven to it.—*Austin Reveille.*

The Mechanics' Institute Fair.—A mee ing of the managers of the Mechanics' fair w held on Tuesday evening, July 9th, and th date of tbe opening of the fair was fixed f August 13th. The Superintendent's repo stated that arrangements for the exhibitio were progressing satisfactorily. Two bundr and fifty applications for space had alrea been received. The enterprise will be take up with full zeal and activity on the part of th managers, and a creditable exhibition of indu trial interests will doubtless be secured. It time that all who have good things to displ should hegin at once to prepare for the fai Let them apply for space early and prepa their exhibits in attractive form.

Woodward's Gardens were never more attra ive than at present. Besidea three lions already m tioned, six monster living alligators, aeveral iguanas a a boa-constrictor have just been added. New atars a constantly engaged for the Pavilion exercises. Rates f admission as usual.

Examine the accelerative endowment plan, as originat by the Mutual Benefit Life Insurauce Co., of Newa New Jersey. Assets, $30,633,429.94. Lewis C. Grov President; L. Spencer Coble, Vice-President; Benjamin Miller, Treasurer; Edward A. Strong, Secretary; Bloo field J. Miller, Actuary. Send for circulars to Jans Mtussell, Jr., agent of insured, 224 Sansome St., in Francisco.

Model Maker and Machinist.—I. A. Heald, No Commercial St., San Francisco, (fourth floor).

OUR AGENTS.

Our Friends can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. Tharp—San Francisco.
B. W. Crowell—California.
A. C. Knox—Pacific Coast.
C. N. West—Santa Cruz, Montorey and San Benito counties.
A. C. Champion—Tulare, Fresno and Inyo counties.
W. D. White—San Bernardino county.
J. W. A. Wright.—Tulare, Fresno and Kern counties.
B. E. Lloyn.—Sonoma and Napa counties.
E. M. Denny,—Oregon.
H. E. Hallett.—Mendocino county.
G. W. McGrew.—Santa Clara county.
Wm. M. Brewer.—Black Hills, Dakota Territory.
Richarn Allen.—Britiah Columbia.
R. D. Nunnally.—Siskiyou County, Cal.
Dr. W. G. Alban.—Amador, Calaveras, Tuolumne and Mariposa counties.

Every new subscriber who does not receive the paper and every old subscriber not credited on the lahel witbin two weeks after payimg for this paper, sbould write personally to tbe publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

To Mining Secretaries.

An amendment to Section 336 ot the California Code, taking effcct July 1st, 1874, provides tbat in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sen through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where he principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips auitable for serving personal notice under tbis law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommed the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Mining Share Market.

In mining circles the most notable incident of the week has been the final connection of the Sutro Tunnel with the Comstock lode, an event that occurred on the 8tb inst., when the great adit broke into the soutb drift of the Savage on the 1640-foot level. Upon connection being made a strong current of air set in from the tunnel passing through the underground works of the Savage, perceptibly reducing the temperature and improving tbe ventilation of that mine, affecting also in some degree tbe air in tbe Hale & Norcross and the Gould & Curry adjoining. That the lower chambers of these and perbaps other mines near the inner extremity of the tunnel would be thus benefited was a result to be inferred, but that the advantages would be so marked and immediate was hardly expected. The next tbing in order will be to render tbis deep lying adit available for purposes of drainage, an end that can be easily reached by the several companies mentioned, but which in the case of those further removed from its terminus will require considerable time and a corresponding expenditure of money to open drifts or otber communications for the passage of the water. In fact, lateral tunnels, such as are called for by Mr. Sutro's contract with the mining companies, will have to be run for this purpose, these being necessary also for tbe removal of ore, the introduction of timber and such other underground supplies as may be required by the various companies located along the line of the mother lode. These all form a part of the work undertaken to be constructed by Mr. Sutro, and must be brought to completion before he can exact of the mining companies the two dollars per ton royalty stipulated to be paid by them in consideration of the benefits to be derived from the use of the tunnel. Moreover, these companies will be likely to call upon Mr. Sutro to complete the tunnel according to the dimensions originally agreed upon before complying with their part of the contract. Without this bow can the tunuel be used for introducing timber or taking out ore, one of the objects contemplated by its construction and provided for in the contract between these parties.

As yet only a "header" or small tunnel has been advanced to the Comstock, tbe most of the main structure, 10 feet by 12, remaining to be built. As this tunnel would never be used for these purposes even if finisbed, after the above proportions, it is probahle that it will remain incomplete, the owners thereof abating something of their demand for royalty, while the mining companies agree to reasonably compensate them for its uses for ventilation and drainage.

In the mining share market little has transpired of interest, the street being without life, sales limited and prices tending downward.

Semi-Annual Bullion Receipts.

Wells, Fargo & Co. bave furnished the press with their usual quartsrly statement of the movements of treasure through their various express agencies on this coast. The receipts at San Francisco from January 1st to June 30th, 1878, were as follows:

Dore Silver Bars—	
Interior	$21,505,500
Mexico	438,600
Total silver bullion	$21,944,100—$21,944,100
Gold Bars and Dust—	
Interior	$ 7,003,300
Coastwise	361,800
Mexico	69,000
Total gold bullion	$ 7,434,100— 7,434,100
Total bullion	$29,378,200

The above amount sbows an increase of $3,684,000 over the receipts for the same time in 1877, and $4,000,000 in excess of 1876. In fact, the amount is the largest ever reported during tbe first half of any year.

It is now pretty evident that the total bullion product for this coast will be larger this year than for any preceding year. and that it will exceed the estimates made by the Director of the Mint by fifteen or sixteen million dollars, that official having fixed the entire product of gold in the United States at $45,000,000, and of silver at $38,950,000, being $83,950,000 for both metals, whereas the yield of this coast alone will probably exceed $100,000,000.

The Fair Season.

The following is a partial list of the coming fairs. We shall be pleased to add to it if readers will send us the dates and locations of their respective exhibitions:

San Francisco Mechanics' Institute, San Francisco, August 13th to September 14th.

California State Agricultural Society, September 16th to 21st, inclusive.

Oregon State fair, at Salem, October 8th to 18th, inclusive.

Nevada State Agricultural, Mining and Mechanical fair, at Reno, October 7th to 12th, inclusive.

Montana Agricultural, Mineral and Mechanical fair, at Helena, September 23d to 29th, inclusive.

Sonoma and Marin district fair, at Petaluma, September 23d to 28th, inclusive.

San Joaquin valley district fair, at Stockton, September 24th to 28th, inclusive.

Northern district fair, at Marysville, September 23d to 28th, inclusive.

Golden Gate district fair, at Oakland, September 9th to 16th, inclusive.

Napa and Solano district fair, at Vallejo, September 3d.

Monterey county district fair, at Saliuas City, October 15th to 19th inclusive.

Siskiyou county fair, at Yreka, October 2d to 5th, inclusive.

El Dorado county fair, at Placerville, September 13th to 15th, inclusive.

Santa Clara valley fair, at San Jose, September 30th to October 5th, inclusive.

Stanislaus County Stock Orowers Fair, at Modesto, October 9th to 11 h inclusive.

Southern California Horticultural Fair, at Los Angeles, October 14th to October 19th, inclusive.

Southern California Agricultural Society's Fair, at Los Angeles, October 14th to October 19th, inclusive.

Training Schools.

President Elliot, of Harvard University, has well said that "the welfare of the universities depends upon the welfare of the training schools." Our State cannot yet boast of a stalwart university. One manifest reason is that the schools which furnish the students for the University either do not take time enough to do their important work well or else lack the qualifications to accomplish what they attempt.

The signs of the times indicate that these foundation defects in the higher education will soon be eliminated. Foremost among the agencies quietly at work solving this all-important problem is, as it occurs to us, the Golden Gate Academy at Oakland.

This institution has just completed the seventh year of its history. Its years and its work entitle it to rank among the permanent educational forces of the State. The first class of pupils prepared within its walls has just graduated from the State University of California. Next year, Yalo, Amherst and Dartmouth will graduate others of its students. It claims to do foundation work in education according to most approved standards. With equal diligence it aims to expand the character into the highest type of noble manhood. Recognizing also the paramount importance of a sound body in order both to the highest mental development and to the best fruits of such culture in life, it has provided a well-equipped gymnasium for daily exercise and a brief military drill, to emphasize the method and system which should characterize the true student. Its instructors are educators hy profession. Its building is a model of comfort, convenience and architectural eleganco. The founders and guardians of this acadomy are many of them graduates of the famous Phillips' Academy, of Andover, Mass., which has recently so worthily celebrated its centennial. It is their purpose to make the Golden Gate Academy like unto this "foremost of Eastern training schools." May the completion of its centenary he as greatly honored.—*Argonaut.*

FRISCO.—The Frisco reduction works started up with their new boiler on the 11th ult., and up to the 28th, with some interruption, and turned out eight hars of silver, valued at $9,030. They are working from 10 to 15 tons of ore every 24 hours. The machinery is working well now. The chloridizing furnaces will he completed next week, and, from the present indications, the pioneer leachers of Utah, Messrs. Harries & Tischer, will make a success of their works here. The Frisco smelter has been continually running on Bonanza ore, turning out over a car-load every 24 hours, and having quite a lot of hullion on the dump. The C. C. company's smelter had heen running up to yesterday, and has shut down for repairs, and over the Fourth of July. They have also hullion on their dump. The Cave mine, owned hy Godhe & Co., is looking well, and they are hoisting and shipping ore daily to the Frisco smelter. The Hedges, adjoining the Cave mine, we are informed, is to be purchased and worked hy a party of capitalists. The Bonanza continues to look well and the working shaft has been connected with some of the lower works. They are shipping ore daily to the Frisco and company's smelter and the leaching works.—*Salt Lake Tribune.*

BUFFALO HORN, the present leader of the Bannocks, is well known in this city and throughout all the region of country embraced between the Sierra Nevadas on the west, the Missouri river on the east, the Pacific railroad on the south and the Dominion of Canada on the north. He is a half-breed, and has always heen friendly to the whites. Two years ago, during the Black Hills campaign, he was Crook's chief scout, and in that position outranked even such men as Wild Bill and Captain Jack Crawford. He is thoroughly familiar with the strategetical tactics of the United States troops, brave to rashness, and hardy heyond even the usual run of Indians. He will prohably not lay down his arms until absolutely driven to it.—*Austin Reveille.*

THE MECHANICS' INSTITUTE FAIR.—A meeting of the managers of the Mechanics' fair was held on Tuesday evening, July 9th, and the date of the opening of the fair was fixed for August 13th. The Superintendent's report stated that arrangements for the exhibition were progressing satisfactorily. Two hundred and fifty applications for space had already been received. The enterprise will he taken up with full zeal and activity on the part of the managers, and a creditable exhibition of industrial interests will douhtless he secured. It is time that all who have good things to display should begin at once to prepare for the fair. Let them apply for space early and prepare their exhibits in attractive form.

Woodward's Gardene wers never more attractive thau at present. Besides three lione already mentioned, six monster living alligatora, eeveral iguanas and a boa-constrictor have just been added. New etare are conetantly engaged for the Pavilion exercices. Rates of admission as ueual.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assete, $30,533,420.94. Lewie C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulare to James Munsell, Jr., ageut of insured, 224 Sansome St., San Francisco.

MODEL MAKER AND MACHINIST.—I. A. Heald, No 514 Commercial St., San Francisco, (fourth floor).

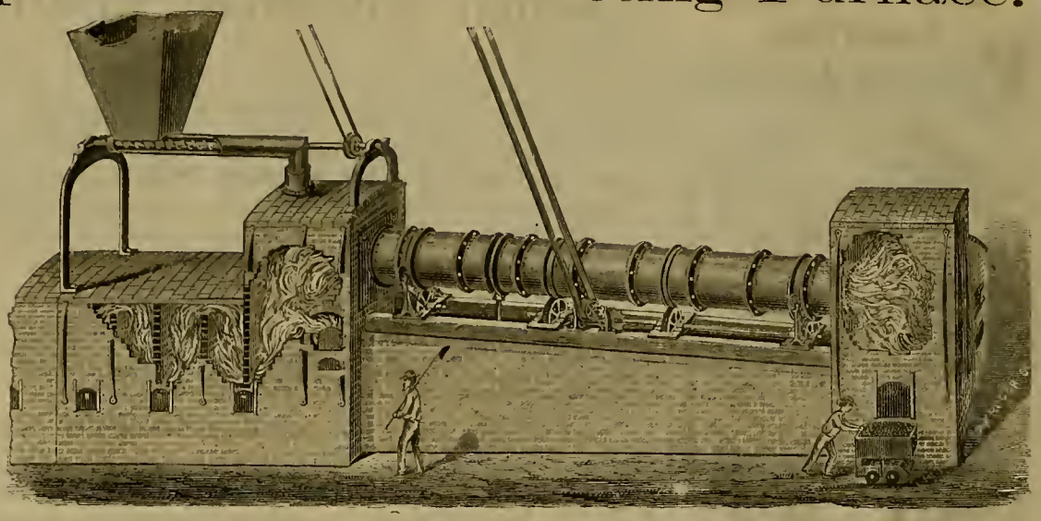
Howell's Improved White Roasting Furnace.



This cut represents the most improved construction of this unrivaled Furnace, the superiority of which over all others as regards cost and capacity, as well as the economical and thorough oxidization and chloridization of ore, is now generally conceded.

In this Furnace, as covered by the Howell and White patents, are combined the three acknowledged requisites for the thorough and economical roasting and chloridization of ores.

First.—Continuous progression through and discharge of the ores from the furnace—while in the meantime they are, by being constantly showered through the heated air and gases within it, exposed in the greatest possible degrees to their reducing action.

Second.—Subjecting the ores to this showering process any length of time that may be necessary, according to the character of the ore, for its thorough reduction. In passing through the furnace it ordinarily falls about 1,000 feet, all the time in direct contact with the flame.

Third.—Increasing the heat on the ores as they are progressed through the furnace.

In this respect this furnace excels all others, as in none of them are combined all these essential requisites. It will chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade

The first cost as well as the cost of operating it is less than that of any other furnace of equal capacity.

It requires no especial skill in management that cannot be readily acquired by any one capable of conducting an ordinary silver mill.

We manufacture various sizes adapted to a five, ten or twenty-stamp mill, and will furnish plans by which any competent mill man can erect and operate it.

This furnace having the full or partial brick lined cylinder, embraces the devices covered by the patent to John Howell, as well as the original devices covered by the White patents, has been erected and operated successfully at the following mines in California, Nevada, Arizona and Montana: Camanche, Jefferson, Leopard, Utah, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry, Independence, Endowment and Alice. At least ten of them are now in active and successful operation, in some cases reducing ores of the most refractory character.

These facts are a sufficient attestation of the merits of this furnace.

The undersigned, with Mr. John Howell, are the sole owners of the Howell patent, and they have perfected arrangements with him, and also with Mr. J. M. Thompson, who is owner of an interest in the White patents, and as such is possessed of as full and perfect rights and powers under the same as the patentee himself, by which they have acquired the exclusive right to manufacture these furnaces for the Pacific States and Territories. We hereby *caution* all parties against purchasing the same from any others but ourselves, or the said Howell or Thompson, as we shall prosecute all parties infringing upon the same. For particulars, price and terms, address

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system and intimate acquaintance with the subjects of inventions in our new community. All worthy inventions patented through our Agency will have the benefit of a description or an illustration and explanation in the MINING AND SCIENTIFIC PRESS or the PACIFIC RURAL PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Advice and Circulars Free. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior.

NOOK FARM.
Families wishing to spend the summer in the country will find this a cheerful home, and beautiful scenery of such endless variety as tempt to healthful exercise and recreation. We furnish good accommodations and an excellent table. Good fishing and hunting on the premises. Two trains from San Francisco, per Vallejo and Napa Valley Railroad, pass the Station daily.
Address, E. B. SMITH, Rutherford, Napa County, Cal

SAN FRANCISCO, SATURDAY, JULY 20, 1878.

VOLUME XXXVII Number 3.

The Leaching of Silver Ores at Baranca, Mexico.

The wet processes are proving daily to be more and more applicable to the cheap extraction of metals from their ores, and we are glad to find that our German engineers and metallurgists are introducing them upon our coast. We are indebted to Mr. Weherling for a description of the process used at Baranca, in the State of Sonora, Mexico, where there is situated one of the foremost reduction works of this kind.

The ore worked is a fahl-ore, with zinchlende, galena and iron and copper pyrites. The gangue is quartz and the ore averages $150 silver, with only a trace of gold. It was crushed dry formerly by a 10-stamp battery and now by the Bruckner ore pulverizer, described in our issue of July 6th, 1878.

It is then roasted to drive off the sulphur, antimony and arsenic, and to change the silver into a chloride, for which purpose 5% to 7% of salt is added. A Bruckner roasting cylinder is in process of erection, but the roasting is accomplished at present by three reverberating roasting furnaces, with four hearths, arranged in the form of steps, the ore being introduced near the flue, and being moved downwards along the successive hearths, till it reaches the hottest part of the fire, where it is discharged. The fire is carefully regulated, so that the ore does not sinter, and it may be discharged as porous and fine as possible. Each of these reverheratory furnaces roasts four tons in 24 hours.

The roasted and chloridized ore now consists essentially of oxide of iron and quartz, chloride of copper and zinc, chloride of lead and chloride of silver, with a trace of gold, which is too small to be worked for. This ore is transferred to the leaching tanks, which are 10 feet in diameter, three feet high and hold eight to 10 tons of ore. The tanks are, of course, provided with false bottoms, covered with common white sheeting, and with a cock to draw off the liquors. The tanks are then filled with *cold* water. This is for the purpose of removing the salts of copper. Some of the chloride of lead is also removed, but not all. But the soluble copper and zinc are entirely removed, and from the solution the copper is precipitated by means of iron. In some reduction works, leaching with hot water is preferred, as it more perfectly removes lead chloride, but the experience at Baranca is that the salts of lead which remain are not injurious, but rather beneficial at a further stage of the operation, as will be seen presently.

After all salts soluble in cold water have been removed, the residue consists essentially of the quartz and iron oxide, chloride and sulphate of lead and chloride of silver. A cold dilute solution of hyposulphite of sodium is then poured upon the ore and left until all the silver is in solution. A small amount of chloride of lead goes into solution also.

The solution is then run into a tank placed beneath the leaching tank, and a solution of polysulphide of calcium is added until no further precipitate forms. This precipitate, which is essentially sulphide of silver with a little lead, is filtered off and, after drying, roasted in a small reverberatory furnace, until the sulphur is all removed in this way as silver bullion of 650 to 700 fine is produced. This is mixed with lead and litharge and cupelled in a Mexican cupelling furnace to a bullion 998 fine. For this reason the lead which is thrown down with the silver as sulphide is rather beneficial than otherwise, as it assists in the cupelling operation. The Mexican cupel furnace is very similar in its construction to the German cupel furnace, but smaller. Its hearth is fixed and is about three and a half to four feet in diameter. Wood ashes are used instead of marl, and it is said to work satisfactorily.

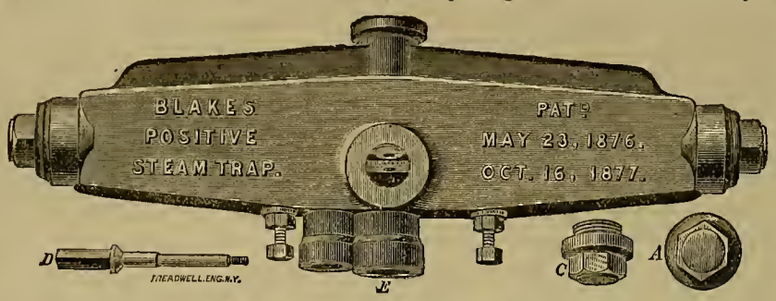
It will be seen that the addition of calcium polysulphide each time to the mother liquor slowly changes it into hyposulphite of calcium, when seems to work quite as well as the corresponding sodium salt, and as long as the solution is kept in use, constantly regenerates itself by the polysulphide of calcium added.

From all that we can learn, Mexico seems to be no field for a person who is dependent upon his own labor for his support. Labor brings a very small sum in that country. A man with a capital of $10,000, or a party of three or four with that sum who understand the practical working of silver ores, might find it profitable. But, at the same time, one should be pretty sure of a good return for his time and money who is compelled to take the risks and inconveniences of life in such a country.

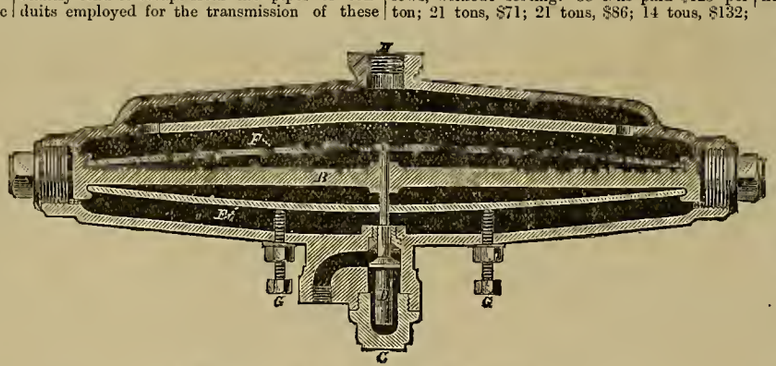
Non-Conductors of Heat.

It now appears probable that before many years shall elapse, most buildings requiring to be artificially warmed will, in all considerable towns and cities, be heated by hot air, steam or water, conducted through pipes from some general source of supply. This plan of furnishing warmth has already been introduced in several places with such gratifying results as warrant the belief that it will rapidly come into general use. Steam for motive power will also come in like manner to be distributed from a great center of generation to points where required for use. As the heat will constantly tend to escape from the pipes or conduits employed for the transmission of these elements, the obtaining of the cheapest and most perfect non-conducting material practicable will become a desideratum. Recourse to various substances has already been had and doubtless others will come to be employed for this purpose. Not long since Messrs. Hopper & Evans patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a new improvement in fire-resisting and non-conducting compounds, which, though especially intended for the lining of safes and fire-proof vaults, would probably be found well adapted to the service above alluded to. As evidence of its non-conducting properties it has been subjected to some very crucial tests of its powers in this respect, papers having remained in a safe lined with this compound for several days while under a white heat without injury. As a covering for boilers and steam pipes this material has been found to largely check the radiation of heat, and in this direction the patentees expect a wide field will open for the employment of their invention. It is, in fact, here that they count upon its becoming of the greatest utility. The benefits to small manufacturers, machinists and all others requiring the aid of a limited but cheap and ever ready motive power being wholly incalculable, as the transmission of such power to distant points with the least possible loss becomes a matter of the first importance. The inventors who may be able to largely contribute toward that end can hardly fail to reap a bountiful reward. As Messrs. Hopper & Evans have attained that object, their compensation is assured.

THE BANNER MINE.—We have been shown some very fine rock from the Banner mine, Mosquito gulch, Calaveras county, owned by J. P. Spaulding & Co., and which will start up again in a short time. There has been some $9,000 laid out on the mine, it having fine new hoisting works, with 25-horse power capacity. There is also a 10-horse power engine and Cornish pump, large enough to handle all the water to the 500 level. They have another No. 3 steam pump and 300 feet of five-inch pipe. There is also a first-class kit of blacksmith tools of every description for use about the mine. A track has been laid and cars supplied to deliver ore. Over $14,000 has already been taken out of the mine, the ore working as follows, without sorting: 38 tons paid $125 per ton; 21 tons, $71; 21 tons, $86; 14 tons, $132; 12 tons, $125; 39 tons, $53. Since this ore was milled the mine has been closed on account of an unfortunate disagreement and a mortgage. The difficulties will soon be removed, however, and the mine will soon start up again. We hope to see this valuable mining property running shortly to full capacity.



PARTS OF BLAKE'S POSITIVE STEAM TRAP.



SECTIONAL VIEW OF BLAKE'S STEAM TRAP.

RETURNED. — We announce to interested friends that Messrs. Dewey and Ewer, publishers and proprietors of the PRESS, have returned from their Yosemite excursion, and are at their posts of duty again. They are refreshed by the respite from business and by the outdoor life which they have led. They desire us to return thanks to all the friends who showed them kindness during their sojourn in the country. As the trip was one for recreation, we do not expect our travelers will do much, at present, in the way of descriptive articles, but the information which they secured during the journey will doubtless work to the advantage of the PRESS in many ways.

The Blake Steam Trap.

We give herewith illustrations showing the construction of "Blake's Positive Steam Trap," made by the Augell & Blake Manufacturing Company, 202 Greene street, N. Y. These steam traps are largely used in manufacturing sections and have proved very satisfactory. In this steam trap there are duplicate leaf huckling springs which are carried at their ends by a loose intermediate metal bar or holder, having an inferior expansive action to the spring, and are combined, for operation or control of the valve, with an inlet arranged to connect with opposite ends of the trap. It also consists in a combination, with the duplicate leaf huckling springs and their bar or holder, of adjusting and supporting screws on which one of said springs rests, and the valve of the trap having its stem connected with the other of said springs. In a trap constructed in this manner, the valve is closed by the huckling of the spring, and opened by the straightening of them, the distribution of the steam over the whole length of the spring is insured, every facility is afforded for cleaning and repair, and a perfect and sensitive action generally is obtained.

Fig. 1 of the engraving shows the parts to be removed for cleaning, should sediment collect in sufficient quantities to require it. *C* is the cap which must be first removed. *E* is the valve box from which the cap is removed, and *D* is the valve stem which must be next removed. The valve seat and the stem *D* should then be thoroughly cleaned, and the stem *D* replaced. In replacing the stem it should be screwed up to a shoulder on end of the stem, and the cap *C* then replaced. *A* is the plug which covers the side of the trap, and is not always removed in cleaning, unless a large amount of sediment should collect in the trap.

Fig. 2 shows sectional view of trap. *F F* are the two brass leaves or buckling springs; the expansion and contraction causing the trap to operate. *B* is the casting for holding the springs; *C* is the valve cap; *D* is the valve stem; *G G* are the set screws for adjusting trap when being put together; *H* is the inlet.

Among the advantages claimed for this trap are that it has a much larger opening than a float trap, since it does not open against the pressure of steam. It will drain a larger amount than ordinary traps. It is adjusted when made and all parts are made in duplicate. The device is always ready for operation, working equally well under high or low pressure. It will be perceived from examination of the engravings that it is positive in operation, a particularly desirable feature. Trap No. 1 is 14 inches long, six inches high and two and a half inches wide; cost $7.50. No. 2 is two feet long, nine and a half inches high and three inches wide, costing $10. For further particulars the manufacturers may be addressed as above.

MESSRS. PARKE & LACY advertise in another column a large list of articles which may be seen at their mining machinery depot. They keep on hand air compressors, rock drills, steam and hand pumps of various kinds, machinists' tools, fire engines, chemical engines and other articles too numerous to mention. The Burleigh rock drills, for which they are agents, are in extensive use on this coast and in other parts of the world, some of them having been used by Henry Meiggs in his railroad engineering works in Peru. The machinery depot of Parke & Lacy is well worth a visit from all who are interested in mechanical devices.

TERRIFIC cloud bursts are common in the Black hills, where one recently inundated a large tract of farming country, sweeping away ox teams and drowning one man. They have also done much damage to the track of the Union Pacific railroad.

COL. MACKENZIE'S invasion of Mexican soil has caused considerable excitement, the people believing that Mackenzie acted under a wide construction of his orders, and that the object was to raise a border war for annexation purposes.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Ore Reduction in Arizona.

[Correspondence of the PRESS.]

Ores Adapted to Concentration.

At Picket Post, Pinal county, are situated the concentration works of the Silver King company, this being the nearest point to their mine, at which water in sufficient quantities for the use of the works could be obtained. Owing to the success that has attended the working of the ores of the Silver King mine by the Frue concentration process, after failurs to treat them hy amalgamation, concentration has come to he looked upon as the only method by which the ores of this district generally can be successfully worked. This method of handling ores has the merit of being cheap, simple and expeditious, the objections to its employment being that it is incomplete and applicable only to certain varieties of ore. It is used with great advantage to separate, by meaus of specific gravity, all ores having a crystalline structure, from their gangue being especially well adapted to the concentration of sulphurets. The Silver King ores contain large quantities of sulphurets of silver, lead, antimony and copper, with a sprinkling of carbonate of the latter, about 20% of the silver existiug as chloride or "dry chloride," as distinguished from horn silver. These sulphurets are crystalline and readily break from the gangue under the stamps. Thus they are practically all saved, hut the dry chloride being light and exceedingly friable is, at the same time, carried over with the tailings and lost unless rescued hy another process. Were the metal all contained in the sulphurets not more than 3% or 4% would he lost. With mines occurring in the limestone formation, however, entirely different conditions are presented. There is a large group of this class of lodes hordering Queen creek on the north, the ores of which are characterized hy the presenee of gray carbonate of lead in considerable quantities. This mineral carries the silver which blackens it, hut does not otherwise alter its appearance or fracture. It is amorphous or entirely homogeneous in structure, and therefore cannot he concentrated, because no matter how fine it be pulverized, each grain still possesses the same specific gravity, and the only result of concentration will be a separation of the coarse from the fine particles. It is proposed, hy parties interested in these mines, to employ this process in the treatment of this ore, hut experience will, I fear, demonstrate to them, as it has to the writer, the folly of the undertaking. How this ore really should be handled remains to he determined. It is not to he presumed that it will amalgamate, and, though it carries a fair proportion of lend, it is not rich enough in silver to pay for smelting where wood and iron (its requisite flux) are so far distant. Still there it may he and is even prohahle that the carhonate of lead will run into galena as soon as eonsiderahle depth is reached in these mines, when concentration ean he practiced upon the advantages.

Another Formation and a Different Ore.

Further south across Queen creek, which cuts through the silver-hearing helt, the proportion of lead contained in the ore is so small that this metal no longer interferes with amalgamation. Here the prevailing ore is horn silver, in itself not well adapted to concentration, while the admixture of tbe dry chloride is too great to admit of a profitable application of this process. Continuing south we find the carhonate of lead decreases, while that of copper increases, until this latter heeomes the predominant metal. A certain percentage of copper has always heen considered advautageous in amalgamation, and even when present in such ahundance as to depreciate the quality of the bullion this is not a serious trouhle. These argentiferous copper ores will in fact very likely be found useful to mix with other ores iu preparing them for amalgamatiou, which will surely be the process employed for their reduction until the mines reach considerahle depths, when the ores may change and other means for treating them will come into use. The opponents of this process point to several unsuccessful attempts wbich have heen made at employing it, hut to this it may be replied that the ores experimented on were, with one exception, taken from mines lying in the eastern or gneiss formation, all highly sulphureted and carryiug lead, antimony and arsenic in such quantities tbat no skillful metallurgist would undertake their treatment without roasting. The result of tne other trials have never been made puhlic, though it was hinted hy one who ought to know, that a very high percentage of the silver was saved, and that the work was discontinued because the quality of the ore did not come up to the owner's expectations—a reasonahle solution, inasmuch as it rarely happens that a miuer estimates his ore at less than twice its value. Experiments made with a hand mortar on many of the ores south of Queen creek have shown that they amalgamate as high as 88% of the fire assay, and as this is hoth simple and conclusive, it is suggested that interested parties make trial of it.

Picket Post, Pinal Co., Arizona, July 8, 1878.

One Hundred Million Dollars.

A Splendid Triumph of Mining.

On Tuesday last there was a shipment of hullion from the Bonauza mines which completed the mighty aggregate of $100,000,000 shipped from those mines. The exact figures were, from the California $40,517,552.20, and from the Con. Virginia $59,493,532.85—a total of $100,011,085.05. From this sum the California has paid 26 dividends, aggregating $28,080,000, and the Con. Virginia has paid 46 dividends, aggregating $41,040,000, making a total of $69,-140,000. There have heen, since the last dividend was declared, shipments amountiug to $670,655.98, which will swell the dividends $440,000, leaviug the full amount of dividends $69,580,000, or within a fraction of 70% of the whole gross product of the miues. These are tremendous figures, and are altogether unprecedeuted in mining. Turn them about, or analyze them in any way, and the result is magnificent. The yield is equal to one-sixteenth of the interest-bearing portion of the national debt; it is equal to the value of the property of all kiuds in an average city of 125,000 inhahitants; it is more than the value of all the real and personal property of this State, and the comparisons might he extended indefinitely. This amount has heen taken from a little spot of ground less than 800 feet in length, and from 60 to 300 feet in width. Aud the marvelous deposit is still yielding priucely sums. As one looks upon the figures, he finds himself wondering why there are any poor in this world, and why so loug as gold and silver will purchase any luxury and all reasonahle service, there are so many who are in pecuniary distress. The thought is cured, bowever, by reflecting that in all the mining of the world no other such success was ever won before. For five years, from 1867 to 1872, a eompany worked the ground all the time, expending $161,340.41 upon the property without realizing one eent in return. At last it was forced to give way, and on the 11th of January, 1872, the property fell to the present management. These men expended $277,150.12 on the property before realizing one dollar from it. It was a stuhhorn fight against the heat aud the barren porphyry—a steady pouring out of gold on a hope, which continued altogether eight years, and which would have been ahandoned in any other eountry but this, and hy any other class of men in the world except Nevada miners. Call it judgment, sagacity, faitb, luck, or what you will; it is a faculty, or rather a combination of faculties which exists nowhere else ou earth. The old stock (only 108,000 shares for each mine) was worth hut $2 per share, and some who per force accepted it for services rendered, hewailed their hard fortune. Since then it has made them richer than they ever dreamed of being, and tbeir word is held in great estimation hecause of their shrewdness in purehasing honanza stocks when they were low.

At last in a drift which was run from the Gould & Curry shaft through the Best & Belcher miue into tho Consolidated Virginia, the crest of the honanza was cut, explorations followed, and the more work that was done the more ore was exposed, until at length in the summer of 1874 it was fully revealed that an ore deposit had been discovered that exceeded in extent and richness auything ever before found in a mine. Ou Octoher 18th, 1873, the first shipmeut of hullion from the Consolidated Virginia was made. That was three months less than five years ago, and now tho product as we have shown has exceeded $100,000,000, almost seven-tenths of which have heen in profits. Of the whole amount ahout 45% has heen gold and 55% silver. The yield of these two mines bas drawn the eyes of the whole world to Nevada. It has shown as was never before shown the possihilities which lie within the grasp of lahor, pluck and judgment in our country. It has lifted up the credit of the United States among the nations of the earth; it has revealed the possible time when the world's commercial capital may he removed from the Eastern to the Western hemisphere. Its sudden mingliug with the world's money arteries gave them for a time an unnatural hent. It made the few dwellers on the Pacific coast appear as greater producers than ten times their number of people anywhere else in the world round, and the addition was not in an article which the world competes in raising or manufacturing, but in that material which the world accepts as the perfect representative of values. While this has been going on, thousands here have found profitahle employment; thousands in Californ.a have heen furnished work and profit in forging machinery and providing supplies, and still the work is progressing, and still the stuhhorn rocks are giving up their treasures. Better still, tbis uuearthing of treasure at depths so profound has given others faith and courage, and the result, we helieve, is that other bonanzas, perhaps larger than the one we have heen considering, are about to he revealed. Many have tried, many have succeeded, and many after tremendous struggles have nobly failed. Foremost among the suceessful stand two men who are entitled to most praise. They came here years ago. They brought nothing but clear heads, stout hearts and strong arms. They went to work as common laborers, and to-day they justly stand the foremost miners of the world. They are entitled to their position, for they earned it fairly, keeping all their contracts in the meantime. Their names make a fitting close to this article. They are John W. Mackay and James G. Fair.—*Virginia Enterprise.*

Overman Mining Company.

The annual meeting of the Overman silver mining company was held on the 11th inst. at the office of the corporation in this city. There were 30,436 shares of stock represented. The following officers were elected: Geo. W. Beaver, President; R. Wegener, Vice-President; R. F. Morrow, Jos. Clark and Sol. Heydeufelt, Trustees; Geo. D. Edwards, Secretary; Charles Forman, Superintendent.

Mr. Heydenfelt is the only new man on the Board, the others having served during the past year. The annexed financial statement was submitted:

Receipts and disbursements of the Overman silver mining company for the fiscal year ending July 11, 1878.

DISBURSEMENTS.

Overdraft of July 12, 1877	$117,950 90
Bills payable	70,000 00
Advertising assessments, less amount received from delinquents	166 00
Interest on overdrafts	13,694 41
Labor	124,635 10
Wood	61,649 87
Timber	9,546 60
Supplies	66,632 85
Ore crushing	3,394 20
Bullion discount	540 32
Office expenses	5,929 20
Expenses, less discount on silver coin	11,462 60
Suspense account	867 37
Bills receivable	12,000 00
Cash in hands of Superintendent	405 86
Total	$498,925 48

RECEIPTS.

Balance July 9, 1877, since paid	$ 634 43
Assessments	441,838 60
Bullion production	7,452 66
Ore sales	3,127 75
Real estate	15 00
Pumping machinery sold	12,000 00
Suspense account	50 45
Cash account overdrawn July 11, 1878	33,756 59
Total	$498,925 48

GEORGE D. EDWARDS, Secretary,
San Francisco, July 11, 1878.

The new engine which was paid for during the last fiscal year, cost $159,000 in this city, and a sum nearly equal to that was expended to put it in position at the mine. The officers report that the payment last year for this machinery, aeeount for the overdrafts in the foregoing statement. At the annual meeting in 1877 the indebtedness of the company was $190,000.

ICE IN THE COMSTOCK MINES.—Tbe miners engaged in re-timbering the Consolidated Virginia shaft are only able to work a few minutes at a time, and in order to do this are obliged to use immense quantities of ice. They not only swallow ice water by the gallon, but also pour it over each other hy hucketsful. Without iee nothing could he done in the lower levels of our mines. When work was first commeuced on the Comstock ice was the last thing any one would have thought of as an article necessary to be used in miuing. When it first hegan to be used not a few looked upou the furnishing of ice water to miners as a bit of high-toned extravagance. Many stockholders thought it was a luxury that might be withheld without much inconvenience to any one. It was thought to he next thing to furnishing the men ice-cream. But as the heat increased, it soou became apparent to all who knew anything at all ahout the matter that ice was an article of prime necessity. Now the heat is so great in many places that men cannot remain in them without ice. Without ice the drinking water would soon attain a temperature equal to that of the air—from 110° to 130°—and men eannot he expected to swallow water that is almost hoiling hot. Since the opening of the Comstock mines ice enough bas been cousumed in them to make an iceberg as big as Mount Davidson.—*Territorial Enterprise.*

EUREKA, NEVADA.—The *Leader* gives the yield of tbe mines and furnaces for the month of June and for the present year in this district as follows: During the month of June, crude hullion was shipped from Eureka district, valued at $731,000. In the same period the Richmond company forwarded fine dore hars valued at $226,623.62. The value of lead sent forward was estimated at $175,000, and the ore and flue dust shipments will add $70,000 more, making a grand total of $1,202,123.62. This is ahout the same yield as during the month of May, or, to he eorrect, about $40,000 less—a fact accounted for by its heing a short month. From the first of January to date, a period of six months, the total yield will aggregate $7,000,000—a sum largely in excess of last year's total yield. This is a good showiug, and places us secoud on the list of silver-producing districts.

UTILIZING THE GREAT CATARACT.—Some of the water of Niagara Falls is to he carried in pipes to Buffalo, and there used instead of steam power for driving various kinds of machinery. A company has heen formed with a capital of $1,000,000, and the work has been commenced. The plain is to divert a sufficient amount of the water in such a way that it will fall into upright iron pipes, compressing the air in them with tremendous force. This compressed air will he directed into strong pipes running to Buffalo, where it will be utilized as a motive power. It is said that experiments have proved the feasibility of the enterprise.

Mining for the Precious Metals in Mexico.

The larger eities of Mexico in the high regions of country were located hecause of their contiguity to mines, at a very early date. The Spanish no sooner found a gold or silver mine than a town arose and became a permanent site. Such towns are now the capitals of flourishing States, and among them are Zacatecas, Guanajuato, Durango, San Luis Potosi, Tresnillo and Tialpujahua. In short, the towns of Mexico are settled on the plan of those of Gold Hill and Virginia City. At the outhreak of our civil war mining alone in Mexico was a progressive industry, and yielded nearly $35,000,-000 a year, or about $7,000,000 more annually than undcr the Spanish in the hest years. Spain repressed all other forms of developments, as wine, wax and oil, designing to make her colony take her own products of that character. For 13 years during the war of independence in Mexico, which was in Madison's, Mouroe's and J. Q. Adams's administrations, the mines were almost neglected. After 1832 Eurcpean companies with large capital entered the country. At Zacatecas, in a harren region 7,978 feet ahove the level of the sea, are 35,000 people, and the outworks of the miues look like feudal castles. Millions of dollars were spent on the mining property of Valenciane, to let the mules walk 500 feet deep in the solid rock, although the product was only $1,000,000 a year. The shaft of the Royer mine is octangular, 1,200 feet deep, 40 feet in diameter, aud blasted as clean as a tunnel. Many of the Mexican mining shafts are faced with hewn stone, and their huildings are palaces.

The Aztecs understood the art of amalgamating the metals with the native mercury, and the Italian sculptor, Benvuento Collini, pronounced an Aztec fish he saw a great work of art, hecause its gold scales on a silver body had heen cast in one mold. In 1557 a Spaniard applied amalgamation to very extensive mining, or two centuries hefore the Freihurg people discovered it in 1786. At Tresnillo, Mexieo, in A. D. 1800, two millions of hundred weight of ore were amalgamated; Spain supplied the quicksilver from her Almaden mine, or 20,000 hundred weight annually. After Mexican independence, England got the quieksilver trade, and ahout 1847 the Rothschilds got it and ran quicksilver up on mankind, cornering the markets of the world. This was stopped for awhile by opening mines of quicksilver in California. Mules and horses at the Mexican mines supply the want of water for power. The Indian lahorers at the mines sometimes carry up 500 weight of ore, climbing up an inclined tree, nicked for steps.

There are four mints in Mexieo; Government takes three per cent. Thousands of mines mines are peddled for sale, aud in many instances common lahorers strike a honanza and grow rich. Mexican recklessness is largely dependent on the mining lottery. In the town of Tasco an Indian and a small foundry proprietor worked $3,000,000 out of an old mine. The white man turned gamhler, and the Indian sbod his horse with silver. The common miners of Mexico are full of Romish superstitions; the agriculturists are quiet and responsihle.

The mining wealth of Mexico is undouhtedly very great. In sulphur it is immense—found in the volcanoes. It produces ruhies, topazes, emeralds, opals, earbuncles, in 20 specified localities. Iu Puehlo State, hetween Mexico and Vera Cruz, mountaius of marhle, porphyry, slate, alahaster, gypsum and litharge are common. It has petroleum, naphtha and coal oil. Coal is found near Vera Cruz and in the State of Pueblo, but it is not plentiful nor good. There are many mines of lead, ziuc, hismuth and copper, eight mines of quicksilver and several of iron. Gold and silver are worked in a majority of the States.

MANAGEMENT AND PROFITS OF THE RICHMOND MINE.—This mine, situated at Eureka, Nev., is owned in England. Not long since the shareholders sent out a committee to examine into its affairs and report thercon, a service which they performed with great thoroughness, their report being very lengthy, and going into the past history and conduct of the property with much minuteness. While admitting that the administration of the mine had, as a whole, proved a success, they still found fault with tbe manner in which the superintendent, Mr. Robert, had managed some portious of the business. Iu replying to this part of the report one of tbe shareholders, Mr. W. Gahhott, takes occasion to point out some of the results that have attended Mr. Rrohert's management, remarking that the mine has already returned £4 11s. 6d. dividends upon each £5 share, or 18s. 3½d. in 1£ upon the eutire capital invested, the mine heing at the present time in good condition. This is more than can he said of any other Anglo-American mine, except Sierra Buttes, which has returned 19s. in £1. No other mine of this class has returned more than a few shillings—really 2s., or 3s. in £1, if they have entered the dividend list at all, and the shareholders should he cautious not to "improve" the management so effectually as to deprivo themselves of future dividends altogether. It would not be the first time that such a result has been achieved. Moreover it should not be forgotten that the mine did not yield profits previously to Mr. Prohert takiug control; that the dividends have been fairly regular ever since, and that the mine is now earning (takiug the last six months' working to estimate upon) over £210,000 a year, or about 78% per annum profit upon the entire capital of the concern.

MECHANICAL PROGRESS.

Proving Chain Cables.

Commander L. A. Beardslee, U. S. N., writes a communication to the *Iron Age* upon the proof strain of chain cables. There are few articles in the whole range of mechanical construction upon which more implicit dependence must be placed, and upon the perfection of which human life and property is so largely risked. Tables showing the amount of strain which good cables ought to be able to bear were made, but unfortunately these tables are incorrect, and in some cases worse than useless, since they impose strains which are greater than the elastic limit of the metal, and which, in chain of the larger sizes, do serious and permanent injury. Up to the time when the United States Board undertook the investigation of the subject, the only information obtainable was that derived from the British Admiralty proof tables and the less known United States tables. Commander Beardslee points out very clearly the fact that the former are incorrect, and that even the latter are not wholly accurate, although the strains imposed are not above the limit of elasticity of the metal. He says the United States Board appointed to test iron, steel, etc., has thought it advisable to prepare from the data collected a new proof table, in the construction of which full consideration has been given to the strength and elastic limit, and to the variation in strength, due to variations in the reduction by the rolls.

And it is considered that by the adoption of this table, cables can be proved to such extent that the presence of defective links may be discovered, and not to such an extent that the very proof shall produce defects which may not be discovered in time.

Working Power of Belts.

Mr. Robert Briggs writes to the *Polytechnic Review* concerning estimates of the working power of belts under different conditions. He says: In their best condition, all belts are worked under the least strain which will transmit the desired power with steadiness. An irregularity of motion is the first indication of the slipping of the belt from inability to transmit under a given tension, and the skilled workman will give it no more tightness than just enough to drive by. It has been found by the experiments of Mr. H. R. Towne and the writer, that under such conditions, any and all leather belts in good working order exert a frictional hold on their pulleys of about 58% of the pressure of the belt upon the surface of pulley at any given place, for a maximum, or about 42% of this pressure in good practice under the ordinary conditions of atmospheric temperature and moisture.

The strain on a single belt can then be taken at 66⅔ pounds per inch of width; or, rather, an ordinary lacing of the lacing holes may be assumed to be durable in service when this strain per inch of width on the tight side of the belt is not exceeded. These figures, derived from experiment, have been corroborated by numerous tests of belts in use, with indicated or measured power, made and compared since the publication of the experiments.

The new unit of value, which I propose, is that derived by the multiplication of the diameter of a pulley in inches by its width in inches, and the result by the number of revolutions per minute. Diameter × width × revolutions.

THE ART OF MOLDING.—At a meeting of the King's College Engineering Society, Mr. E. W. Anderson read a paper on this subject. He gave the following general rules to guide the molder in the running-in of the metal in molding, which are not altogether novel but will bear repeating: 1. Choose, if possible, the thickest part of the casting for the runner. 2. If the casting is deep, run in the metal at the bottom. 3. Where the casting has a flange in the form of a pipe it is generally preferred to run the metal in at the flange; but this case is subject to rule 6. 4. When the casting is thin, and has many branches, or when it is of great length, it is advisable to run in the metal in the center. 5. Care should be taken to choose a place in the mold so that the metal will have no tendency to wash any part away in its first rush. 6. (This rule may be called a continuation of No. 5.) The metal should not be allowed to fall from any hight upon a weak part of the mold, or it will be liable to break down portions thereof.

AMERICAN WORKMANSHIP.—In the course of a description of a visit to the French war vessel, the *Richelieu*, a foreign correspondent remarks that it seems impossible for one to go anywhere without some specimen of American ingenuity cropping up; accordingly, on the quarter deck of the *Richelieu* was a Gatling gun beside a mitrailleuse. It is astonishing, the correspondent adds, how tasteful Americans are in everything relating to machinery. The Gatling, beside the dull, heavy, somber French piece, looked like a piece of jewelry, its steel and brass flashing like gold and silver in the bright sunlight of the Mediterranean. And this is the more noteworthy because the French have a decided bent toward decoration and generally make things look as well as possible.

French and English Locomotives.

According to Paris correspondence, the exposition gives a good opportunity to contrast the French and English styles of locomotive building. An English authority sees it in this light: To allow a rough comparison, it may be said that the English locomotive is the stout, sleek horse, well groomed, with smooth flanks, while the French is the lean, shaggy donkey, its sides overhung by a couple of panniers. The comparison, inapt as it may be, perhaps, is no exaggeration whatever. One of the aims of designers of French locomotives, as here exhibited, seems to be to turn a great part of the inside out—to disembowel them, so to speak. They have outside cylinders and an overhanging valve gear, which gives them a very "uncanny" look to eyes accustomed to the sight of the round, full-bodied English engines. However, leaving alone their outward appearance, all these locomotives appear to be beautifully finished, in a style not at all inferior to that of the best English makers. Notably is this the case with the locomotives exhibited by the Eastern and by the Southern of France railway companies. There is one engine, sent by the Eastern, of such extraordinary aspect, as well as size, that it cannot fail to attract general attention. It has four coupled driving wheels of no less than seven feet and ten inches in diameter, and between the wheels is a flat-topped fire-box of prodigious size, which gives the whole an uncouth appearance, increased by a long connecting rod, attached to the outward cylinders. The valve chests are on the top of the cylinders, and the valves themselves are worked by outside eccentrics, while there is reversing gear running in the shape of a dome over the huge fire-box. It is difficult to give, without long detail or pictorial illustration, a clear description of the ungainly shape of this engine, but some idea of its size may be formed by stating that its width, from one side to the other near the driving wheels, is about 10 feet. To one acquainted with English work, the locomotive of the Eastern of France looks extremely old fashioned; but an examination of it shows that it is a very recent produce of French engineering skill. It is most beautifully finished; every bolt and screw is a piece of admirable workmanship; and it almost seems as if the whole construction is more the turn-out of makers of chronometers than of the rougher artisans who build up steam engines.

Registering Founders' Patterns.

At the last meeting of the Eastern Stove Founders' Association, decided action was taken in favor of registering patterns in the Patent Office in Washington, so that the manufacturers of these patterns shall have exclusive benefit of their designs. A bill to this effect has been already introduced in Congress, which provides: First, by placing upon such patterns and castings the word "registered," together with the date of such registration. Second, by causing to be recorded in the Patent Office a statement specifying the names of the parties desiring the protection, their residence and place of business, together with a general description of the pattern to be registered, and duplicate photographs or drawings of such patterns. Third, by making payment of the fee of $20, in the same manner and for the same purpose as the fee required for patents. Fourth, by complying with such regulations as may be prescribed by the Commissioner of Patents. The Stove Founders' Association ask that the certificate of registration as above prescribed shall remain in force for 17 years from the date of such registration. Such certificate, during the period that it remains in force, shall entitle the person, firm, or corporation registering the pattern to the exclusive use thereof, to this extent, that no other person shall lawfully use castings made from said patterns as patterns for the production of other castings. The proposed law also prescribes penalties for infringement.

HAND AND MACHINE STOKING.—At an adjourned meeting of the Manchester (Eng.) scientific and mechanical society held recently, a discussion took place on the subject of mechanical stoking, dealt with in a paper read at a previous meeting by Mr. Bowes. The general opinion was that hand-firing, if properly and intelligently carried out, was more efficient than mechanical stoking, so far as it has at present been developed, and some complaints were raised that the latter process often results in injury to the boilers. It was, however, admitted that mechanical stoking might be made the means of effecting considerable improvement in the prevention of smoke, and in the more economical use of coal.

DIRT-BURNING LOCOMOTIVES.—The first one of the new coal dirt-burning locomotives was recently placed upon the Pennsylvania and Reading railroad after a few days' satisfactory trial. The other three are waiting for their boilers, which are being made. Coal dirt-burner No. 408, which was built about a year ago, was taken back into the shop a few days ago, and will be supplied with a new and smaller boiler. The present boiler will be used for raising steam in heating one of the shops of the company. Trial on the road has shown that it is not necessary to have such a large boiler for locomotives using the smallest kind of coal.

SCIENTIFIC PROGRESS.

Gun-Powder as a Fog Signal.

Prof. Tyndall is continuing his study of the subject of fog signaling, and the *Popular Science Monthly* gives the account of his latest conclusions. The following is concerning the use of gun-powder: The more rapid the shock imparted to the air, the greater is the fractional part of the energy of the shock converted into wave motion. And, as different kinds of gunpowder vary considerably in their rapidity of combustion, it may be expected that they will also vary as producers of sound. This theoretic inference is completely verified by experiment. In a series of preliminary trials conducted at Woolwich, on the 4th of June, 1875, the sound-producing powers of four different kinds of powder were determined. In the order of size of grain they bear the names respectively of fine-grain (F. G.), large-grain (L. G.), rifle large-grain (R. L. G.), and pebble-powder (P.) The charge in each case amounted to four and a half pounds, four 24 pound howitzers being employed to fire the respective charges. There were 11 observers, all of whom, without a single dissentment, pronounced the sound of the fine-grain powder loudest of all. In the opinion of seven of the 11, the large-grain powder came next; seven also of the 11 placed the rifle large-grain third on the list; while they were again unanimous in pronouncing the pebble-powder the worst sound-producer. These differences are entirely due to differences in the rapidity of combustion. All who have witnessed the performance of the 80-ton gun at Woolwich, must have been surprised at the mildness of its thunder. To avoid the strain resulting from quick combustion, the powder employed is composed of lumps far larger than those of the pebble powder above referred to. In the long tube of the gun, these lumps of solid matter gradually resolve themselves into gas, which, on issuing from the muzzle, imparts a kind of push to the air, instead of the sharp shock necessary to form the condensation of an intensely sonorous wave.

ANOTHER FRANKLIN EXPEDITION.—An event worthy of record is the sailing on the 19th of June, from the port of New York, of the schooner *Eothen* to search for the relics of the Franklin expedition. Accounts in the New York papers, after marking out the northward course of the vessel, state that the party will go up to the Gulf of Boothia, and traverse a great deal of country which has not hitherto been explored. It is believed that an island will be found in the Gulf of Boothia which is not upon any chart, and which was described by the Esquimaux who visited Capt. Barry in 1872 and 1876, and gave him spoons marked with Sir John Franklin's crest. The cairn from which they obtained them, and which, they said, contained many other things, including books, is supposed to be upon this island. The search party cannot set out on their journey until there is plenty of snow to make good sledging. On reaching their destination, they must wait for the snow to melt before making their investigations, as it would be impossible to dig through the immense masses of frozen snow in an Arctic winter. After the work of exploration is completed, snow must be waited for again in order to return to the vessel, and then open water must be waited for before the latter can start on its homeward journey. The *Eothen* is only 87 feet in length, 23 feet breadth of beam, and eight and one-half feet depth of hold. Her hull has been overlaid to the chain-plates with oak planking an inch and a half thick, and her stem has been greatly strengthened to prepare her for the encounter with the ice.

THE SAGACITY OF ANTS.—Prof. Leidy, in a recent article, quoted by the *Journal of Chemistry*, states that, in order to ascertain whether a house be had just entered was (as he suspected) seriously infested with red ants, he placed a piece of sweet cake in every room. At noon every piece was found covered with ants. A cup of turpentine oil being provided, each piece was picked up with forceps, and the ants tapped into the oil. The cake was replaced, and in the evening was again found covered with ants. The same process was gone through the following two days, morning, noon and night. The third day the number of ants had greatly diminished, and on the fourth there were none. He at first supposed the ants had all been destroyed, but in the attic he observed a few feasting on some dead house-flies, which led him to suspect that the remaining ants had become suspicious of the sweet cake. He accordingly distributed through the house pieces of bacon, which were afterwards found swarming with ants. This was repeated with the same result for several days, when, in like manner with the cake, the ants ceased to visit the bacon. Pieces of cheese were next tried with the same result, but with an undoubted thinning in the number of ants. When the cheese proved no longer attractive, dead grasshoppers were supplied from the garden. These again proved too much for the ants, but after a few days' trial neither grasshoppers nor anything else attracted them; nor has the house been infested with them since.

ETHNOLOGY.—We read that some changes have been recently made in the arrangement of the specimens of the relics and varieties in the American Museum of Natural History. In the second story the greatest changes have been made with a view to devote the gallery entirely to ethnology and archæology, and all except four cases there are now occupied with specimens illustrating that branch of research. It is intended that each case containing ethnological material shall also have a map of the region occupied by the tribe or nation to which it refers, and photographs of the present appearance of localities where the specimens were found. In carrying out the plan for a map of each region once occupied by ancient tribes that have left relics, are now inhabited by people whose implements are quaint and curious, Prof. Bickmore, the superintendent of the museum, has been led towards the construction of a large map of this country, colored to represent its former occupation by distinct races of Indians. This work has compelled great research, but the results are sufficiently striking to repay the labor. Some curious facts have already been elicited in the course of this inquiry. Thus it is found that mound-building survived as a custom to a date fully within the historic period. The collection of implements and ornaments from various tribes, and the relics from their graves, will prove of service in tracing their history. But this museum offers the additional advantage of representing in adjoining cases the handiwork and tools of the natives of remote countries and uncivilized islands. The opportunity is thus given for comparing the work of uncultured people on either side of the globe.

SCHOOL FOR SILK CULTURE.—Samuel Chamberlain writes to the *Polytechnic Review*, concerning a plan of a silk school, farm and village about 30 miles from Philadelphia. He believes that the failure to introduce silk culture in 1840 was chiefly due to the want of perseverance. The three years of actual trial (for the rest was only speculation in trees) were not sufficient to carry it on to success. Business, like machinery, must be carried over the dead-points. A school, farm and village, whose continuance will be maintained for some 16 to 20 years, will secure a permanent source of knowledge, example and instruction from which the culture will extend year by year. It will not be overthrown, as formerly, by causes outside of the silk business. It will keep the subject before the public through advertisements. It will at all times provide eggs, trees, hooks, etc. The educational advantages will be very great. We are now endeavoring to introduce the industrial schools of Europe for instruction in the mechanical arts. But they have possessed silk schools for nearly 100 years; through them have obtained and retained till now the silk business of the world! It is more than strange that such schools, urged by M. D'Homergne in 1835, should not have been long since established in this country. The present effort ought to have the immediate support of every intelligent and far-sighted capitalist; for through it we shall draw the silk business of the Western World to ourselves.

THE DREAMING OF PLANTS AND ANIMALS.—Mr. Francis Darwin, lecturing at the London Institution on the analogies of plant and animal life, said: There is one, but only a fanciful resemblance, between the sleeping plants and animals, namely, that both have the power of dreaming. I have been sitting quietly in the hot-house at night, waiting to make an observation at a given hour, when suddenly the leaf of a sensitive plant has been seen to drop rapidly to its fullest extent and slowly rise to its old position. Now, in this action the plant is behaving exactly as if it had been touched on its sensitive joint; thus some internal process produces the same impression on the plant as a real external stimulus. In the same way, a dog dreaming by the fire will yelp and move his legs as if he were hunting a real instead of an imaginary rabbit.

INSECTIVEROUS FIG LEAVES.—Prof. Mechan, in the New York *Independent*, says: Mr. Darwin has the Drosera. The difficulty of obtaining leaves for experimental observation is now removed, for it has been discovered that the common fig leaves have just the same decomposing tendencies. The fig leaf has long been considered rather rough as an article of underclothing on our first parents; and, now that its power of cooking flesh is discovered, it will, no doubt, receive renewed attention from scientists of the John Jasper type.

PURE ZINC.—The *Polytechnic Review* notes that pure zinc, for laboratory use, is of great importance in the reduction of ferric to ferrous salts in volumetric estimations of iron with chameleon. Here it is indispensable that the zinc should be free from iron and carbon. Bohannon suggests the preparation of pure chloride of zinc by the wet process, from metallic zinc, and the precipitation of its iron by ammonia. The chloride thus obtained is to be reduced by means of metallic sodium in a porcelain crucible.

GOVERNMENT SURVEYING.—There are at present four Government surveys in progress. Two under the direction of the Engineers' Department, one commanded by Lieut Wheeler, and the other by Lieut. Clarence King; the other two under the auspices of the Department of the Interior, and commanded by Prof. Hayden, and the last by Mr. Powell.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned

California.

AMADOR.

PLYMOUTH.—*Ledger*, July 13: The Empire, formerly the Phenix, still runs to its full capacity, and the rock now being crushed is very rich and of the best quality. A very large reservoir is to be constructed above in Pi-Pi valley, which will give employment to several hundred men. This work will be commenced in a few days. Hayward, it is rumored, intends opening a new mine south of the old Phenix. Nothing of importance is being done in the old Hite mine. The Oneida is working up some excellent rock that was taken from the 600 level. The tunnel in the 900 level is being retimbered, and when this is accomplished it will be run north until the ledge they are in quest of is struck. Everything about this institution evidences thrift and good management.

MONTERICHARD CLEAN-UP.—This mine had a clean-up this week, after a 19 days' run. The result was very flattering, the yield being nearly one-fourth more than any former product—being the effect of richer rock in the lower level.

THE PENNSYLVANIA is running full blast, and the outlook favors the idea that it will continue to run as long as there is a hope of its paying. From the character of the ore now passing through the mill, sanguine expectations are founded of a permaneut and paying mine. There is plenty of ore in sight.

THE CROWN POINT mine and mill at Orytown are idle. The last run paid, it is said, over $3 per ton, which leaves a small margin for profit, after paying expenses. Parties are talking of leasing the works, confident that with a yield of $3 per ton they con realize a handsome thing by the speculation.

OTHER MINES.—In the stretch of country along the mother lode, lying between the Gover and Bunker Hill mines, the Hazard claim is located. No work has been done upou it worth mentioning, although mining experts regard it as among the most promising location on the mineral belt. It belongs to A. Hayward, and rumor has it that it is to be started up forthwith. The Seaton mine has come to a standstill, in consequence of litigation caused hy a party of jumpers. Messrs. Manon and Pharis are still running the creek mining claim with good results. Gage's chlorination works are running on full time witb good results.

CALAVERAS.

COMPLETED.—*Chronicle*, July 13: Sliter & Hoey's mill, recently put on their claim in Old Woman's gulch, is completed. The pipe to convery water for motive power is also laid and everything in readiness for beginning operations on next Monday. The battery is composed of five stamps. The new incline is also finished to tbe gravel, so there is notbing to hinder taking out the "precious" as fast as they want to. Tbere is every indication that the Sliter & Hoey will prove a permanently profitable piece of property.

CLEAN-UP.—Moser & Co., proprietors of the Big Bonanza hydraulic, on Tunnel ridge, opposite Sport hill, cleaned up lately. We did not learn tbe exact figures of the yield, but hear it was large—way up in tbe tbousands. Judging from all accounts the mine is paying handsomely.

FRESNO.

ORO FINO MINES—*Republican*, July 13: It has long heen known tbat good mines exist in the mountains nortb of tbe San Joaquin river, and on the heads of Fresno, Fine, Coarse Gold, and other streams tbat lose themselves on the plains before reacbing a larger stream, but, for some reason, very little has ever been done in the way of practical development. During the past year, under the stimulus of new ownership and a little capital, a lively interest has sprung up in tbis region; new mines have been discovered, old ones reopened, and active operations begun in those being worked. The Fresno company have opeued the Buena Vista mine and crushed not less than 350 tons of ore since the middle of February whicb yielded an average of $40 per ton. The company own five separate leads, and the Oro Fino mine is yielding $300 to the ton. The Hanover mining company, of San Francisco, are receiving and putting up a five-stamp mill on Long gulch, six miles below the Oro Fino mines. Some Spaniards are working a mine within one-half mile of tbe Fresno company's mill and have crusbed 10 tons of ore in an arastra within tbe past 60 days, and took out over $1,000. New ledges are being discovered every day and fine prospects obtained. Placer mines are being worked, yielding from $2.50 to $5 per day to the man.

INYO.

EMIGRANT MINE. — *News*, July 13: Tbe owners of this property continue making improvements. Last week Peter Taylor, Superintendent, went to Independence to complete the purcbase of the old Cerro Gordo water works, consisting of pipes, tanks, steam pumps, etc., wbicb will he used in bringing water to his company's mines. An assessment of 50 cents per share now dne is pretty well paid up. This assessment will amount to $25,000. With it the company can accomplish its undertakings, of moving the mill and increasing it to 10 stamps and bringing in the water.

UNION CON.—This mine has made millionaires of two or three men, working only in a crude way near the surface. It is now determined to work more systematically and develop the miues to a very great depth. To do that requires an increase of machinery and power; hence the present assessment. It is the true way to develop a mining property, as then the burden falls upon all the shareholders alike. There will be renewed life in old Cerro Gordo when this money is collected, and we wish our neighbors up there god-speed.

MONO.

BODIE DISTRICT.—*Standard*, July 18: During the past week there are few important changes to note, although work progresses steadily. Not alone the principal mines, hut many of the smaller ones have prospects that bid fair to eclipse anything yet developed. For a long time the public have waited for depth to be attained in the Standard, Bodie, Red Cloud, McClinton and Black Hawk, and are now satisfied that these are not mere surface croppings and extend only 200 or 300 feet down, but really permanent dividend-paying ones. Not only have they sunk their main shafts from 300 to 600 feet, hut cross-cuts and drifts have been run in every direction, until in some of them the amount of ore now in sight is enormons. Instead of extracting ore, large forces of men have been kept at work opening up and prospecting for other ledges, and, in almost every instance, their efforts have been crowned witb extraordinary success. In the Standard alone, there is ore enough in sight to run their mill for two years, and the rich samples from the Red Cloud show that tbe mine is even richer than ever. The strikes in the Bodie would astouish the most sanguine; and still the developments go on. The Booker, too, comes in for its share of praise, for the recent developments in this mine show conclnsively that the vein is improving in richness as the shaft is driven down. With the 65 stamps which will soon be in active operation, there can he no reasonable doubt but Bodie will be the liveliest camp on the coast. Since the public have become confident of the permanence of the older mines, considerable more prospecting is perceptible, and claims not worked for months are resuming active operations, or forniug corporations for the purpose of developing them. The result of all tbis work must be bullion, and lots of it, even though it simply paid a small per cent.

NEVADA.

MINING ON THE RIDGE.—*Transcript*, July 17: At French Corral the Milton company is washing and running full headed, and handed, and surfacing the debris into the South Yuba river, and reaping the rewards of the cost of their tunnel, $175,000. At these claims will be found all the modern machinery and appliances, with drops, nnderconrrents aud secondaries arranged in the most improved style. The round grizzly hars are here used in place of the flat iron bars. One of the great advantages claimed for which is that they can he easily turned, and by that means loosen any rock that may catch hetween, and also hy turning the bars tbey will wear longer. These bars are three inches in diameter, with either end squared, so tbat a wrencb can be easily placed on to change the distance between them.

ROCKY BAR MINE.—Everythiug is going along smoothly at the Rocky Bar mine. The drifts from the bottom of the incline, which is 280 feet deep, are being driven steadily ahead in both the east and the west ground, and the work of stoping above tbe level has commenced. The ledge shows well in size and quality in both the level and stopes. An air chute is also being raised from the level to tbe surface. In the tribute ground, on tbe first level, the rock continues to look excellent, sbowing free gold plentifully. The yield from the next crushing is expected to show an improvement over tbe last, which went $50 per ton.

PLUMAS.

THE BELL MINE.—*National*, July 13: Since the strike mentioned a couple of weeks since, the company have been steadily at work and new developments have been made every day. An incline has been sunk at the point where the richest rock was found, and also a shaft raised, and botb of these works show the best indications. We saw a candle box full of specimens taken from the upper shaft, and every piece showed an ahundance of free gold. We are more aud more satisfied that the company have one of the hest mines in the State. The mill is now running steadily, and a clean-up made this week from a four days' run gave tbe neat little amouut of 96½ ounces after heing retorted.

THE GREEN MOUNTAIN MINE.—There are two mills on tbis property, one 20-stamps and the other 12, run by hurdy-gurdy water wheels. The whole 32-stamps are run with about 85 inches of water, at a cost not exceeding $10 per day. Every convenience to be had is found in the mills, the entire cost of extracting the ore, conveying it to the mill, aud crushing, not exceeding $2.50 per ton. The rock is brougbt from the mine to the mill on a covered tramway, horses heing employed to draw the cars up to the mine, from which they descend again by their own weight. The mine is being worked botb above and below tbe level of the tunnel. An incline has been sunk, which already has explored the mine to a deptb of 1,100 feet from the surface. At the mouth of the incline, and in the depths of the mountain, an engine is being placed in position, to be used in pumping and hoisting. A tunnel is being driveu from a point on a level with the mill, whicb will tap the mine at great depth. In the meantime the engine will be used. At the bottom of the incline they have a well developed ledge over 30 feet wide, all of whicb is good paying quartz.

SANTA CRUZ.

PLACER MINING AT APTOS.—*Courier*, July 13: Gold mining on the Aptos beach is still prosecuted to a considerable extent. We were this week shown about $10 in gold dust, washed from a ton of black sand at that place last Saturday, by O. P. Wilson and Mr. German. Yesterday morning Dave Rice, of Aptos, came to town, and as we met him he whipped ont a buckskin bag and showed $70 of beautiful bright gold dust, whicb he and two others had washed out on the Aptos beach in six days—averaging nearly $4 a day each. They were able to save only about one-half of the dust, and hence have made arrangements for an apparatus which saves it all. The water is also short, and to remedy this, a steam pump will be brought into requisition to obtain the very necessary material from the creek near by.

SIERRA.

BROKE DOWN.—*Mountain Messenger*, July 13: The Pilocene mine met with a break down last week. The wire rope used to drive the large pump suddenly broke. The small pump was not of sufficient capacity to keep the shaft clear and it filled to within about 60 feet of the top. A new rope was sent up from below, arriving on Saturday last, so that the company have probably been at work several days. The water increases rapidly as they go down.

WORKED OUT.—The Empire mine at Howland Flat is about worked out. We get our information from J. Denoon, Supt.

SISKIYOU.

LINDSEY MINE.—Yreka *Journal*, July 13: This mine contains a good strong vein of fine looking quartz. The wall rock is slate, witb the regular clay streak on hoth walls. The third has been run nearly 200 feet, and in the tunnel the water drips quite freely. The work performed has been executed in the most substantial manner. The quartz taken out of this level and the stopes above paid $45 on the ton. On the 100 aud 200 levels, the rock did not pay more thau $25 to the ton. On the 400 level, developments look very well. This mine was discovered about four years ago, and was worked by the discoverers, Lindsey & Norman for 18 months. Their developments were such by that time that the moneyed men stepped forward and bought an iuterest. At the present time quartz enough is being sent to Johnson's mill for crushing to pay all current expenses, and the balance is piled on the dump.

A FAIR PROSPECT.—Mr. Allen Davis, of Trinity valley, has hauled over a ton of quartz rock, from a ledge which he is engaged in working in his neighborhood. The rock milled is said to have yielded satisfactorily. The ledge from which the rock was taken is about six feet wide, and pays evenly. We hope that it may pay handsoinely, and reward Mr. Davis for his efforts, and indnce others to engage in prospecting and developing tbe many rich quartz veins which we helieve to exist in the mountains of northern California.

TRINITY.

A GOOD YEAR.—*Journal*, July 13: Gold dust is coming in at a lively rate, iudicating a large yield throughout the county. Trinity should this season yield double the amount of the precious metal taken out last year. Miners in the Basin are engaged in cleaning up. The side ditches are looking well.

QUICKSILVER.—The Altoona mine is now turning out a large quantity of quicksilver. The ore here is exceedingly rich, and as it can be mined at little expeuse, quicksilver is produced here at less cost probably than at any otber mine in tbe State.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—Gold Hill *News*, July 17: Daily yield, 250 tons of ore. Sinking the C & C sbaft is making steady progress. It is now down 65 feet below the 1950 level, the bottom still in bard blasting rock and the flow of water strong. The south lateral drift on the 1950 level is being pushed vigorously forward, the face in hard porphyry. It is now in 202 feet. The joint Best & Belcher east drift on the 1900 level is being pushed steadily ahead to reach the east wall of the vein, when a winze will then be sunk downward to the 2050 level, where it will connect with tbe soutb drift on that level from the C & C sbaft. The north drift on the same level from No. 2 winze still continues in low-grade ore. It is now in a distance of 100 feet. The new winze in tbe western ore body, helow the 1650 level, continues in low-grade ore.

CALIFORNIA.—Daily yield, 250 tons of ore. The south lateral drift from the joint winze on the soutb line of the Ophir on the 1900 level, is in a distance of 79 feet, the face still in vein matter. A drift has heen started on the 1650 level from the main northwest drift to connect with the ore stopes, which will greatly aid the extraction of ore at that point. Sinking the C & C shaft is advancing at the rate of 10 feet per day, the bottom in hard blasting rock and the flow of water strong. It is now down 65 feet helow tbe 1950 level.

HALE & NORCROSS.—Much trouble has been experienced. A portion of the air current from the Sutro tunnel was turned through the mine the first part of the week, which greatly increased the heat, and necessitated the putting in of air pipes. The current of air, which was a downcast before, will after this he upcast.

OPHIR.—The great point of interest in the Ophir mine at the present time is east crosscut No. 2 on the 2000 level. Sinking the main incline is making good progress, and opening the 2100 station will be commenced in a very few days more. Repairing the main shaft above the 1465 level is making good progress.

JUSTICE.—The north drift on the 1300 level has reached the Lady Washington line, at which point crosscuts both east and west will he started to-morrow. The ore formation going southward on the 1376 level continues to show a strong improvement. A small amonnt of ore is still being extracted from the old 400 level.

SIERRA NEVADA.—The north drift on the 2000 level is being pushed vigorously forward, the face in favorable vein matter.

OVERMAN.—The east drift from the 1600 station of the maiu incline and the west drift from the bottom of the winze will soon complete a connection which will greatly assist the veutilation on that level. Tbe main south drift from the bottom of the winze on the 1600 level is making steady and favorable progress.

SAVAGE.—The air connection with the Sutro tunnel continues to furuish a strong current of air, the temperature of which is gradually decreasing. The face of the west crosscut on the 2100 level is showing some favorable quartz.

CHOLLAR-COMBINATION SHAFT.—Preparations are heing made for putting in the large pumps. It is likely that these pumps will be put in only up to the 1600 level, and that a connection will be made at that point with the Sutro tunnel, which will save a large amount of the power required to hoist the water to surface.

BELCHER.—Sinking the winze helow the 1900 level is making good headway. The prospecting drifts on both the 2160 and 2360 levels are being advanced as usual.

UNION CON.—The north drift on the 1600 level is now in a distauce of 511 feet, the face still in porphyry and clay. The erection of the blower is completed, and the fan ruuning and is helping greatly the prosecution of the work in all the drifts.

CON. IMPERIAL.—The main north drift in the Alta ground is making steady progress, the face in quartz and vein matter, affording low assays.

BEST & BELCHER.—The south drift on the 1900 level from tbe winze is going steadily forward, the heat in the face being intense.

MEXICAN.—The joint east drift on the Ophir north line is making good progress. The joint Union Consolidated east drift on the north line is also making fair progress.

CROWN POINT.—Retimbering and enlarging the maiu south drift connecting with tbe Belcher mine on the 2300 level is making good progress. The south drifts on both the 500 and 600 level are being pushed steadily ahead.

WARD.—The flow of water gives some little trouble, but is kept down by a steady use of the tanks.

LEVIATHAN.—On the 750 level the soutb drift has run iuto vein matter and is now pushing ahead following the foot-wall of the ore vein. The north drift is following the foot-wall of the vein to the nortbward.

YELLOW JACKET.—On the 2400 level tbe south drift is in 30 feet from the north winze station; face in porphyry and quartz.

UTAH.—The northeast drift on the 1150 level is steadily advancing, the face in vein material. It is now in a distance of 295 feet.

NEW YORK.—The east prospecting drifts on the 1150 level are showing some very favorable quartz and vein matter.

GOULD & CURRY.—The pumps are in place and the connections are being made at the 1900 station level. The large air pipes are now beiug carried down, and it will not be loug before everything will he in complete order.

LADY WASHINGTON.—The north drift on the 1160 level is steadily advancing. The maiu north drift on the 1300 level of the Justice has reached the south line of the Lady Washington, and surveys are being made to-day to locate and start hotb east and west crosscuts on the south line of the mine.

ALTA.—The face of the north drift on the 1250 level continues in a very favorable character of quartz and vein material. Tne north drift on the 1350 level is also making good progress, the face in quartz and low-grade ore. The flow of water in the bottom is strong, but is easily handled by tbe pumps.

BULLION.—Sinking the main incline below the 1840 level is making the best of progress, the bottom still in very favorable vein material. The north drift on the 2000 level is steadily advancing, tbe face in vein matter of a very encouraging character.

TROJAN.—The ore stopes on both the tbird and fourth station levels continue to yield ore of a good quality and look well. There is now on hand at the Vivian mill on the Carson river, for reduction, about 400 tons. The bullion returns from the ore crushed last montb was $15,600.

SILVER HILL.—The north drift on the 900 level is making steady headway, tbe face in quartz carrying spots of ore. The nortb drift on the 800 level is making steady progress, almost tbe entire face in quartz and low-grade ore. The face of crosscut No. 3 from this drift is also nearly all in ore.

JULIA.—An unfortunate breakage of the pump-rod has prevented the progress expected in getting the water out of the 2000 level. Everything is, however, again in good running order. As soon as the level is drained the east

crosscut and the main south drift will be again started up.

SUTRO TUNNEL.—Since completing connection with the Savage workings, the air in the tunnel has vastly improved and cooled off considerably. The header is being steadily advanced toward the Savage shaft, and will be continued not only to the west wall of the great lode, but farther into that wall than any of the mining companies have yet penetrated.

BELMONT DISTRICT.

BELMONT AND EL DORADO SOUTH.—*Courier*, July 13: The work of exploration is being steadily pushed ahead on both these mines, which have now been opened systematically to a depth of over 600 feet. The machinery is all in good order, and the prospect of soon opening up permanent bodies of pay ore is steadily improving.

THE GILA MINE.—The presence of foul air is retarding operations here somewhat. In a short time connection will be made with the canyon tunnel, when a good circulation of air will be had and a better headway can be looked for. The vein in drift continues to look very well, being, as it has been since first struck, about two feet wide of good ore. Assays from the lower and richer portion of it gave $567.36 and $510.60 per ton. No prospecting has yet been done upon the vein either below or above the drift in the shape of winzes or raises, and none can be done till better ventilation is secured. They are at present using a blower which furnishes but a scant supply of air, barely sufficient to run the drift. The stopes in the south drift continue to yield considerable ore, but not in quite as large quantity as for some time past. The mill has been stopped several times in the past five days to make necessary repairs upon machinery, but it is now in good running order again. Bullion product for June, $26,204.25.

JEFFERSON.—Letter of June 22d says: We are making excellent progress in getting the mine free from water; expect to get the 600 level dry to-morrow or next day. To drain the 700 level will be a short job in comparison to the 600 level. If everything continues to work as well as at present, we shall be down in about five days.

REESE RIVER DISTRICT.

MANHATTAN MINES.—*Reveille*, July 13: During the week ending yesterday morning the mill reduced 138 tons of ore of the assay value of $21,368.76. The 675-stope of the Curtis shaft is producing the usual amount of ore, but of a much better quality. The 517-stope carries an extremely large ledge, but of lower grade; the rich ore being in hunches. The 675 east drift is in good ore, which shows that the chimney does not diminish in width as we gain in depth. There is no change in the 670-stope of the Frost shaft, the ore continuing of the same high grade. There is good ore still in the face of the 670 west drift. Timbering winze No. 2 at the 770, and cutting out a station at the 570, is being pushed ahead as rapidly as possible.

PARADISE ORE.—Yesterday we were shown some specimens of fine ore from the Little Humboldt mine at Paradise valley. There were also surprisingly rich specimens from the Red Deer and Big Prize mines in the same district. These samples are full of native silver, sulphuret, horn silver and stedefeltite, and will assay away up in the hundreds. The ledges from which the specimens were taken have been recently opened, and the ore was obtained at a depth of from five to 15 feet from the surface.

GRANTSVILLE.—The Alexander mine continues to show and yield rich ore. Although closed to visitors the ore body is said to be marvelous, and continues as progress is made in the lower level. The work of extraction is being pushed and shipped to the mill for reduction. The site for the new mill, at the mine, has been completed, and the foundation is now in the course of construction. A large portion of the machinery has been shipped from San Francisco, and the balance will soon be on the road. The mill, as we understood while in San Francisco recently, is to start with 20 stamps, with a capacity for 20 more. Quite a little town has sprung up at Grantsville, and although business is not very brisk there at present, if the mine continues to be as good as has been generally represented, a large population will ultimately gather into the new El Dorado.

WHITE PINE DISTRICT.

THE TUNNEL.—*News*, July 13: An entire change has taken place in the Eberhardt tunnel within the past two weeks. The formation is now a soft, decomposed substance, resembling soap-stone, but in reality lime-stone, acted on by some of the chemical forces of nature's laboratory. They are driving 70 feet per week, and are now parallel with the old Eberhardt ground, and about 150 from its end line.

SHUT DOWN.—The King furnace shut down last evening, after a 27 days' run, the result of which, we learn, is highly satisfactory to the parties concerned.

STARTED UP.—The Eberhardt company's mill was started up last Thursday and will make a run, on company ore, of about 60 days.

Arizona.

FROM SILVER BELT.—*Citizen*, July 12: The Isabella mine is yielding for each miner employed $100 per day. The Turk mine ore assayed 546.65 ounces per ton—owned by Wm. A. Holmes. Six men are at work on the Miami, which with that force yields four tons of $200 ore per day. The Hannibal silver mining company are vigorously at work sinking their 400-foot shaft. Shipped 2,104 ounces 950 fine silver from Julius mine.

THE MCMILLEN MINE—A RICH STRIKE.—Since the sale of this property by McMillen and Harris to its present owners, the working of the mine has been confined principally to the rich stratum on the east side of the main ledge. The company seemed satisfied with extracting pure silver from the stratum, and until recently have manifested no disposition to determine the mineral value of the main ledge. Lately a shaft has been sunk on the west side of the main ledge to a depth of 130 feet. A drift from the bottom of this has cut into solid ore eight feet without passing through it. This ore will average nearly $150 per ton. The future of that section of the district depends almost entirely upon the value of this main ledge, and a strike in a large body of rich ore is of course hailed with joy everywhere. The rich stratum yielded large profits to the company, but was of comparatively small benefit to the country. The discovery of a large body of low grade ore in the main ledge would necessitate the building of a mill or two, and the employment of a large force of miners, and the benefits would be largely felt throughout the district. But the McMillen company is always very cautious in its movements, especially where any great outlay of funds is necessary, so if they commence a mill we may be sure they have use for it, and mean to run it.

OTHER MINES.—The Tiptop mill will start up next week. Its owners have abundance of ore and water. Hackberry mill pounding out a great deal of silver bullion. Also the Peck.

TOMBSTONE DISTRICT.—Much of the rock here is immensely rich, going from $300 up into the thousands. Veins are of varying breadth, some as wide as 20 feet. The district is attracting great attention and many are coming in from San Francisco. One mine which had been sunk on only 10 feet, was sold for $10,000 cash, and a number of others had found purchasers at from $1,000 to $5,000 cash. Weather exceedingly hot.

TONTO BASIN.—*Enterprise*, July 13: Recent mineral discoveries in this section of Arizona are of a nature to force the conviction, always entertained, that it is second to no other section of our Territory. Besides its rich and extensive deposits of gold, silver, copper and lead ores, kaolin, a variety of clay used for making porcelain, lining furnaces, etc., was recently discovered, and will, ere long, be tested. Should it prove to be of the right sort, it will be of move value than a rich gold or silver mine. Coal, too, exists in Tonto Basin, and we have the word of F. X. Aubrey for the existence there of rich placer mines. He, while passing through the Basin, in 1853, traded with an Indian for a lump of gold that weighed nearly a pound. He also saw Indians using gold for bullets. Of course, this statement will be taken with due allowance, but it is a well-known fact that the streams of the Sierra Pinta, the Sombrera and other mountains around the Basin contain gold.

Colorado.

THE OURAY MINERAL FARM.—San Juan *Sentinel*, July 11: This property has been sold to New York parties. The original owners received $85,000 for it from Edward Innis, who afterwards received $250,000 for five-eighths of it. The present owners will put up reduction works in this vicinity, which will be a valuable improvement to this portion of San Juan. The property has the finest reputation as an ore producer, of any mine in the southwest. It has been opened in a great number of places, all showing the best of ore. But little of the ore has been reduced, still the mill runs of from 280 to 312 ounces have established its great value. The supply so far seems to be immense, and, as far as proven, has shown this to be the largest body of ore on the surface of any in the State.

Idaho.

LATE DISCOVERIES.—*Avalanche*, July 13: The ore find lately met with on the Florida mountain has infused new life into this district, and will revive business here generally, however the Indian troubles may result. The ore opened up in the Black Jack yields at the rate of $200 per ton, and the lode is steadily improving. The Ellmore mill is turning out crude bullion at the rate of $3,000 per day, and if the rock continues to improve as it has for the past week the daily bullion yield will soon reach $4,000. We have seen times here during the past year when a bar of bullion was a refreshing and novel sight; now we see these bars by the dozen, and ranging in value from $2,000 to $4,000 each. The Florida mountain bonanza surpasses the Poorman and Golden Chariot in their most palmy days. The owners of the Adelma, Messrs. Regan & Crutcher, had a crushing of rock this week at the Ellmore from their new mine, located near the Poorman. The average yield was $125 to the ton, and there is plenty more like it and much better in the immediate vicinity. The Potosi mine is looking first-rate. Dillinger & Upham are working a promising lode in the vicinity of Florida mountain, and all the mines which are being operated in the vicinity are yielding well.

ATLANTA.—The new hoisting works for the Buffalo are on the way from Kelton, and will be erected and in operation before the first of September. The shaft will then be sunk a further depth of 200 feet. At present there are about a dozen men employed at the mine. There is a considerable quantity of rock ont now awaiting crushing. The mill started up last Saturday on Monarch rock. Some 17 men are at work in the Monarch mine, which steadily continues its yield of good rock, and is under judicious management. A new mine is being worked by Messrs. Davis and Peddler, and is reported to have splendid prospects. Geo. Dawes and Stephen Hooker have discovered a new mine about six miles north of Atlanta, and if all reports are correct they have an immense bonanza.

CANONVILLE.—*World*, July 12: The water has fallen terribly during the past two weeks, and the placer mines around here will soon be compelled to stop for the season. In fact Hon. Ben Willson has already shut down several of his claims. Report says they paid him big, and no doubt they did. Stevenson & Noble are still running their claim, but will be forced to stop soon for want of water. Messrs. Sifers & Hallett are working on the Blackbird mine in Charlotte gulch, near Grimes' Pass. John Madden has been at work representing a silver mine up Grimes' creek for the past two weeks. Other men are at work on quartz mines around here, and you may expect to hear of rich discoveries some day. Willson & Whitney will start their mill on Summit Flat as soon as the shoes and dies arrive from the railroad.

News in Brief.

A CHAIN-GANG is to be organized in Santa Rosa.

COL. FAIR, of Bonanza fame, is rusticating at Santa Cruz.

THE army worm is destroying vegetation in Trinity county.

CONTINUED rains with wind and sultry weather create fears of damage, both from lodging and rust, to the wheat crop of Minnesota.

IN the city of New York last week Dr. Carver shot and broke 5,000 glass balls in 500 minutes, but came near losing his eyesight by the feat.

THE recent storm at Pittsburg and vicinity was the most disastrous one, in loss of life and property, which has visited that locality for years.

WILLIAM SUTCLIFFE of New Orleans, who a few weeks ago defeated Frank Pointze in a 24-mile swim, was drowned in the Mississippi river since.

THE British government has cancelled an order for 40,000,000 cartridges, and various other indications point to a stoppage of war preparations.

THE body of Guy Stewart, the boy who was reported missing from Dayton, Nev., about three weeks ago, has been found in the Carson river.

SEVERAL Sutter county farmers, who have threshed their crops, find that the yield per acre is much less than estimated, it averaging from 10 to 12 bushels to the acre.

A RECENTLY stolen safe, with its contents, valued at $270,000, belonging to Michael Richard, or Rathrockville, Pa., has been recovered, with everything intact.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

MAGNOLIA G. M. Co.—July 15. Capital stock, $5,000,000. Directors—John H. Floto, John Persbacker, Thomas A. White, S. H. Raymond and I. J. Harvey.

LADY BRYAN S. M. Co.—July 16. Capital stock, $10,000,000. Directors — Charles F. Smyth, I. F. Thompson, W. S. Wood, Thomas C. Grant and George W. Hazleton.

CON. BLUE GRAVEL M. Co.—July 16. Capital stock, $10,000,000. Directors—E. P. Hutchins, T. H. Wells, J. S. Fields, C. B. Kendell and George W. Osborn.

BOX ELDER CON. G. & S. M. Co.—July 17. Capital stock, $10,000,000. Trustees—R. F. Knox, D. A. McKinley, T. B. Lewis, J. H. Weed and T. H. Johnson.

CRESCENT G. & S. M. Co.—July 17. Capital stock, $5,000,000. Trustees—E. Merrigeld, E. M. Hull, E. B. Marsh, E. L. Montgomery and J. H. Crossman.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Northern Belle, July 8th, $6,500.80; Hillside, 5th, $4,860; Tyho Con., 8th, $4,571.43; Raymond & Ely, 8th, $4,283; Manhattan, 12th, $12,100; Tybo Con., 10th, $4,457.40; Justice, 15th, $15,900; Con. Virginia, 12th, $129,488; California, 15th, $158,035.71; Tyho Con., 12th, $4,564.38; Gila, 16th, $9,639; Hackherry, 17th, $14,000; Independence, 15th, $12,000; Alexander, 18th, $3,799.13.

After the Mines are Exhausted, What?

A worked-out hydraulic mine is naturally a scene of desolation. The desert of Sahara is not more barren. It is a series of sand mounds and rocky ridges. It is the home of the lizard, the rattlesnake and the horned toad. The glorious forests of pine, cedar and white oak, which crowned the original surface, has disappeared, and a sheet of white sand and quartz boulders dazzles the eye that looks on it. It is very natural to ask, "After the mines are exhausted, what?" Nature quietly answers. Ashamed of the desecration accomplished by the hand of man she sets promptly to work to repair the damage. Gentle zephyrs carry on their wings the seeds of forest trees, of wild shrubs and flowers, dropping them on the bare and parched ground. They find a foot-hold with the first rains, and scarcely observed spring up in every nook and corner. Trailing vines stretch their arms forward and throw out their sheltering leaves over the nude earth, and the work of rehabilitation is completed in almost as brief a period as the work of denudation was accomplished. Everywhere in the wake of the hydraulic miner the coming forest is crowding upward. When the hydraulic mines are worked out the ground will be ready again for the horticulturist. For that matter, the miner is gradually preparing himself and his offspring for a new avocation. The hydraulic miner lives now under the shade of his own vine and fig tree. A fruitful orchard is gradually growing in dimensions around him, and before his first occupation will have departed, the new one of fruit-growing will have taken its place. Some of the settlements on "The Ridge" are already notable for the character of the fruit raised in them. And there is no section of the State better fitted for fruit culture and vinticulture than "The Ridge" and its adjacent foothills. It is to this industry it will be devoted after hydraulic mining has ceased.—*S. F. Bulletin.*

A Good Beginning.—The editor of the Pioche *Record* has visited the Hillside mine at Bristol, eastern Nevada, and says of it: "We found the furnace in full blast, running splendidly, and keeping three shifts of workmen attending to it. Hillside ore is found to be just the kind to run through nicely; the only addition that is requisite to make it work is quartz. Each shift of workmen turn out about 60 bars, making 180 bars in 24 hours' run. These bars weigh over 75 pounds each, and the average assay of the bullion is $455 per ton. Up to the time we were there the furnace had been running successfully eight days, averaging from $2,500 to $3,000 per day. Mr. McGee, the manager, stated to us that if he could keep the furnace running for five or six days longer the company would be enabled to pay for everything, including the money advanced by him to purchase the National mine and furnace." Further on the mine is described as looking splendidly, with an abundance of high-grade ore opened.

Largest Shaft on the Comstock.—Experience in mining on the Comstock, says the Gold Hill *News*, has demonstrated the great utility of larger shafts. The extra cost of sinking is comparatively trivial, while the conveniences are much greater. The shaft is the thoroughfare of the mine, and like the principal street of a city, should be of ample dimensions. The largest shaft on the Comstock is the new one of the Yellow Jacket. Its three working compartments are each five feet by six and one-half, and the pump compartment six and one-half by seven and one-half feet. It has been carried down to the depth of 1,560 feet, is vertical as a plumb line and well timbered. It is being constructed for business and to stay. The entire cost of the shaft, machinery, building, etc., up to the present time, amounts to $672,858.08. The company owes on the machinery $65,000, which it has the coin on hand to pay. In convenience of arrangement the works are second to none on the lode.

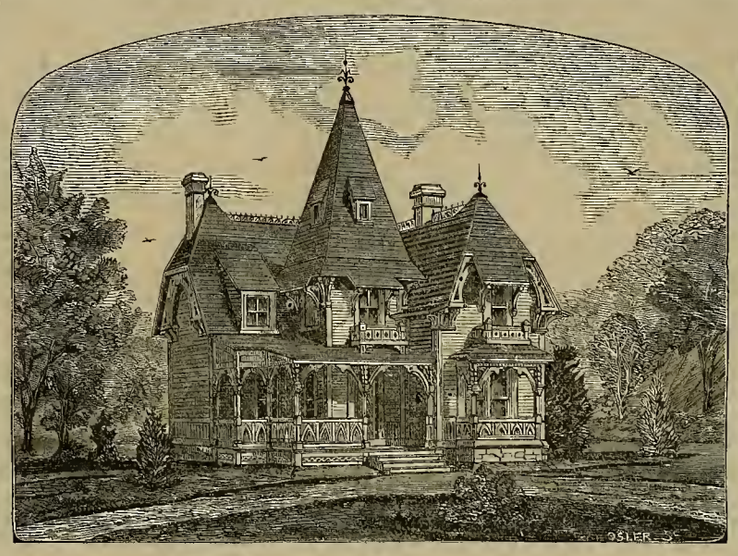
The Idaho mine has been a regular dividend payer for over nine years—its last monthly dividend, the 107th, of $23,250, being paid on the 1st inst. The total of dividends paid to this date is $2,433,000. Of late the company have been making extensive improvements to facilitate the working of the mine. On account of the pay chute tending to the eastward from the main shaft, and to save working through barren ground, a working shaft is being put down from the 10th level 300 feet east of the main shaft. This shaft, 14 by six feet in size, with two compartments for cars and one for ladder and pumpway, is now down 40 feet feet on the ledge, which shows an average of four feet in size. The additional 15 stamps of the mill, making 50 in all, will be ready for work about the first of next month.—*Foothill Tidings.*

Refining Sulphur.—According to the *Silver State*, Henry Sewell, a resident of Winnemucca, Nevada, has been granted a patent for a new process for refining sulphur without fuel or water or iron retorts. He says 250 tons of crude sulphur can be treated at one charge. The furnaces are made of common stone and mortar and cost about $200 each. When running they require but very little attention, and one man can manage two or three of them, as the only work to be done after charging, is to tap them once every six hours. The heat required in running the furnaces is produced by sulphur, from 12% to 15% of which is consumed in refining.

Design for Gothic Cottage.

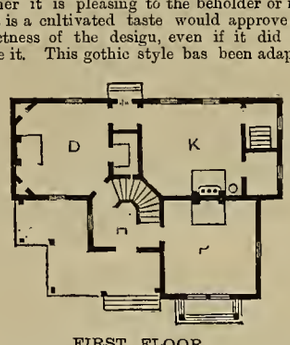
There is now great demand among house builders for departures from the old log cabin or parallelogram model of a dwelling, and features are borrowed from the architecture of all times and lands to secure the coveted diversity. Although the result secured is often very tasteful and beautiful, there are many instances in which the builder has made a jumbled mess of his design and his work offends all correct tastes. We have seen linkings together of different styles of architecture which are almost as out of place as would be a sawed bracket on the Parthenon. We have seen dwellings made up of a mixture of light and heavy orders; as ridiculous as light basket wagons hitched to an elephant.

It is commendable to diversify our styles of buildings, but it should always be done with due regard for two things, first the symmetry of the design, or the harmony of all parts with each other; second, the concord of the whole structure with the surroundings. A picturesque site calls for a building which shall be in sympathy with our character. An ornamental cottage on a rocky promontory would be no more out of place than a light-house on a pretty, flower-laden slope. Let each one consider these things as well as the contents of his purse when he gives the builders orders for his new habitation.

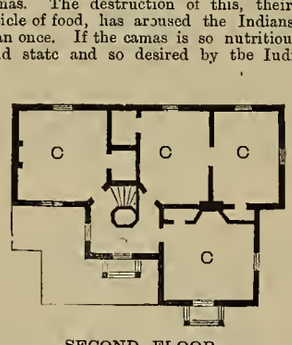


DESIGN FOR COTTAGE IN GOTHIC STYLE.

The gothic cottage, of which we give an engraving on this page, was designed by Isaac H. Hobbs & Sons, architects, of Philadelphia, to meet a demand for something a little out of the common line of cottage designs. It is graceful and picturesque, and is a harmonious design throughout. Of course it is a matter of taste whether it is pleasing to the beholder or not, but it is a cultivated taste would approve the correctness of the design, even if it did not choose it. This gothic style has been adapted to cottage designs in several different ways by Messrs. Hobbs & Sons, and in the hands of skillful designers it gives opportunity mould and modify according to the demands of individual needs, and still retain its truth.



FIRST FLOOR.



SECOND FLOOR.

The cottage shown in the engraving is frame and the roof is of slate or shingles as desired. The estimated cost is in the neighborhood of $3,500. The following explains the lettering on the floor plans and gives the dimensions of the rooms:

First floor—H. hall, 10 by 10 feet; P. parlor, 14 by 14 feet; D. dining room, 14 by 14 feet; K. kitchen, 14 by 15 feet. Pantries and closets are also shown on the diagram.

Second floor—C. chamber over parlor, 12 by 14 feet; C. chamber over dining room, 14 by 14 feet; C. C. chambers over kitchen, 10 by 14 feet. Closets are also shown.

A Big Lot of Quicksilver.—The Virginia *Enterprise* says that 11 carloads of quicksilver has arrived for the bonanza mines. Nine carloads, or 2,050 flasks, were brought to Virginia City, and four carloads, or 450 flasks, were left at mills on the Carson river. The purchase of 2,500 flasks of quicksilver looks like business.

The Camas.

The Sacramento *Record-Union* of recent date contains the following remarks upon the uses and growth of this esculent root. The word is of Indian origin, and should be accented on the last syllable: We have received a specimen of the "camas," the food upon which the Indians of Idaho largely subsist, and which gives the name to Big Camas prairie in Idaho. It is a bulbous plant, throwing up a stalk not larger nor stronger than a wheat straw. This rises, in a wild state, to a hight of two or three feet, and is thick set with small, thin, loose, bell-shaped flowers, which, as we have them, are dried, and contain the seed of the plant. The nutritious part is the bulb, out of which each straw grows. It varies in size from one to two inches in diameter, and in appearance closely resembles the onion, but is free from odor. It is a dry bulb, starchy in quality, and considerably gelatinous. When dry it can be easily pulverized, and, with pulverized grasshoppers, is again dried, and the flour thus made, worked into bread, is said to be highly nutritious. July is the digging season. The bulb grows about four or five inches below the surface of the earth; the digging of the bulb is the only cultivation the ground receives; and the flowers being dried and open when the bulb is dry, the seeds fall out, and the new crop is usually sown by the act of harvesting. We have a few of the bulbs and a quantity of the seed, and if gardeners desire to see what can be done with the plant by cultivation, we will furnish samples on application at this office. Our readers will remember that the camas is the direct cause of the Indian war. The Camas prairies was the great harvest field of the Indians. Settlers plowed up the ground and turned in cattle and hogs—the latter being especially partial to camas. The destruction of this, their chief article of food, has aroused the Indians more than once. If the camas is so nutritious in a wild state and so desired by the Indian, it would seem that the Government might on a thousand or so acres of land cultivate enough to satisfy the demands of the redskins of the plains.

Reworking Tailings.—The Success mill, says the Gold Hill *News*, erected at Washoe to work the 200,000 tons of tailings and slums at that place will start up the last of this week. Messrs. Partridge & Baldwin expect to work these tailings for $1 or $1.25 per ton. As they average about $12 per ton there will be several millions of dollars in the enterprise. The mill will be run by a small turbine wheel. These tailings are the tailings of early days, when millmen did not understand to pursue the nimble sulphuret and refractory pyrite so closely as at the present time. The only wonder is that this mound of pulverized wealth has so long been allowed to rest in quiet.

Suit for Miners' Wages.—The Michigan Supreme Court has just decided a $25,000 suit, in which Mr. Tilden is interested, against him. It was brought by the laborers in some Lake Superior mines, in which he is a large owner, who want to get some wages due them.

A New Superintendent for the Bonanzas.

At a meeting of the Board of Trustees of the Consolidated Virginia and California mines, held in this city on the 8th inst., James G. Fair, for many years past the able and successful Superintendent of the California and Consolidated Virginia mines, tendered his resignation, which was accepted.

Mr. W. H. Patton, Mr. Fair's assistant, was then appointed to fill the vacancy. Mr. Fair's ill health is given as the principal cause of his resignation, although few men with his wealth and circumstances would have retained so laborious and taxing a position as long as he has done. According to the Gold Hill *News*, Col. Fair does not part with the Comstock yet, as he still holds the superintendency of the Ophir, Mexican and Union Consolidated mines. As a superintendent and manager of mines, Mr. Fair has no superior on the Pacific coast. A man of great experience, good judgment, watchful and careful of every detail of his business, energetic and faithful to the interests of his company, his is indeed a place that it will take more than an ordinary man to fill. It looks, however, as if his mantle could not have fallen on one more fitted for executing his arduous duties than Mr. Patton, who is not only one of the ablest engineers of the State, but has for years past been engaged in milling and mining in all its different phases, aside from having for many months past filled the position of assistant to Mr. Fair, so that in taking charge of these mines he starts in, not as a new hand but perfectly familiar with every detail of the work. As long as a change must take place, it certainly could not have fallen into better hands.

Owyhee Mines.

From Mr. David Adams, of Silver City, we learn that the excitement attending the recent Indian raids had so far subsided as not to interfere materially with mining operations, which are being carried on much more extensively and with better prospects than for years past. The families who had left their farms on the creeks between Silver City and the Bruneau are still in town, but the men have returned to look after the crops and the stock. Property of all kinds is looking up, and business generally is improving.

Two discoveries of rich ledges on the War Eagle mountain, near the Poorman have been made recently. One of them is a very rich ledge discovered by James R. Crutcher, the ore from which assays as high as $3,000 per ton. Another near the same locality, located by Hill & Douglas has produced ore worth $2,000 per ton.

Very rich ore has been struck in the Black Jack mine, where a force of 30 men are employed. The mine is well opened and in good condition. Large quantities of good ore are being extracted from this mine and crushed at the Elmore mill, which will be kept running on ore from the Black Jack during the entire season.

Extensive operations are going forward on the Potosi, which is improving regularly. Other smaller enterprises are being pushed ahead with good prospects. Altogether, the outlook is much more favorable than for a long time past, and miners and business men are greatly elated at the improved condition of the camp and the brightening prospects.—*Idaho Statesman.*

Don't go to Washoe.—The Virginia *Enterprise*, having before advised men in search of employment to avoid seeking it in the Comstock mines, repeats the warning in this wise: Again we say that it is useless for miners or workingmen of any kind to come to this city or any place along the Comstock expecting to find employment. We have hundreds and hundreds of men here now who can find nothing to do; not miners alone, but men of all trades. Hundreds of first-class miners—men inured to the beat of the lower levels and men who have a perfect knowledge of timbering, pump work and work in rock of every kind—who are begging for work.

Contracting for Convict Labor.—H. G. Livermore, contractor for the employment of 350 convicts at the branch State prison, near Folsom, for five years, paying therefore at the rate of 50 cents per man, has filed in the office of the Secretary of State his bond in the sum of $250,000, with Horatio P. Livermore as surety. The contract provides that the prison building must be completed before the contract goes into effect. Within 30 days after the completion of the building 100 of the 350 prisoners are to be received by the contractor; within two months, 100 more; and within three months, 150 more.

First Foundry in Arizona.—The McCracken foundry was fired up June 9th for the first time, running about two hours and turning out 2,500 pounds of shoes and dies for the battery and wheels for the ore cars. It was a perfect success from the start. G. W. Edgerton made the patterns, and the castings show that he made them well. The next run will be on tappets and more shoes and dies. The foundry will be of immense convenience to the local mills and to those at Hackberry and Mineral Park. Anything broken can be replaced by new castings without sending to San Francisco. *Yuma Sentinel.*

The Big Camas Prairie.

The Omaha *Herald* of June 21st represents Gensral Crook as saying in the interview with a reporter of that paper, that the Big Camas prairie is a mere swamp, covered with water from April tn June or July, and representing it as ouly fit for the production of the camas plant, which constitutes, as is said, the main source of food supply for the Indians. The right nf the Indians to this valley and the injustice nf the whites in occupying it is pretty plainly intimated, as well as its worthlessness for any othsr purpose than that of contributing to the sustsnance of savages.

It is difficult to believe that General Crook would say what is attributed to him; certainly he never would if he had seen the section in question, or was acquainted with its topography and relation to the adjoining settlements and thoroughfares.

The Big Camas prairie is not a swamp, as is represented, but a beautiful and fertile valley, from 25 to 30 miles in length, with an average width of at least 10 miles. Within these bounds there is every variety of surface, nearly all of which ie susceptible of cultivation. There is no portion of it which could not be easily drained and converted into grain fields if needed. It has all been surveyed iuto sections at the expeuse of the tax-payers of the natiou, and should be now open and ready for settlement. It lies contiguous to the Overland stage road, leading from Boise City to Kelton, and also to the stage road connecting the Overland road with the mines iu Alturas county. Its exclusive occupation by Indiaus merely for the purpose of hunting and diggiug roots is impracticable in the preseut condition of the country, and would prove a source of constant trouble and danger. The settlers have thus far used it ouly for grazing purposes during the summer months, but the advaucing settlements will soon make it desirable aud necessary for the site of permanent homes. The Indians covet it, not because it preduces the camas plant, hut because it is contiguous to the roads and settlements. Were it isolated from these, they would never make it a summer resort as they dn. As to the destruction of the camas by the hngs, this has merely heen used as a pretext for begging and levying contributions upon the whites, as all the hogs that have ever been on the prairie have never diminished in any perceptible degree the yield of the camas root. This year there were no hogs on the prairie, or next to none, while the cattle men and stock raisers were disposed, as heretofore, to share with the Indians whenever they killed a heef, or had other provisions to spare. The Indians were asked to say what their iutentions and wishes were with regard to the stock remaining upon the prairie, and whether they wished them removed, when they said no; the stock might remain on the prairie. But from pure "cussedness" the Indians had determined to go upon the war path this summer; and had the prairie with all the etock upon it been abandoned to them at the start they would have gone to war all the same.

Whatsver settlement may he made with the Indians, the Big Camas prairie can never be given up to their sole occupancy as it is a part of the surveyed puhlic domain, which is needed for the use of civilized beings. As to a joint occupancy with the whites, that is equally impracticahle, unless the Indian is willing to ahandon his trihal peculiarities and become a farmer, stock raiser and citizen, and of this there is not even a remote prohahility. If it is camas that the Indians want and must have, there are hroad areas in many parts of Idaho where it grows and decays without ever heing disturbed by them. Let them dig it where it is easily found in abundance, and where there would he no conflict with settlers. It is wrong to represent and treat the Indian as a heing who must live upon wild roots, or be fed at the expense of the toiling taxpayer, whom he kills and rohs for his summer amusement.—*Idaho Statesman.*

Populating the Valley of the Yellowstone.—The rapid manner in which this valley has heen settled shows how war becomes the pioucer and promoter of immigration. At the point on Tongue river, where General Miles encamped in 1876, there is now a town with a population of 1,000. The battle fields of Custer and his men are occupied by farmers, and the country from which Sitting Bull was driven is in the peaceful possession of the pioneers of civilization.

Canadian Pacific.—The track of the Canadian Pacific is now laid, and engines running from Winnipeg to Selkirk, a distance of 21½ miles, and from Selkirk eastward, on section 14 of the main line, 50 miles. This gives 71½ miles, all told, in working order within Manitoha. At the eastern end of the line, Messrs. Purcell & Ryan have pushed their work to a very advanced point, and they expect to have the road huilt 113 miles westward from Thunder bay this autumn.

Gorham Blake, of Boston, who made a fortune in California mines, has lately beught a great tract of land in Georgia, and after prospecting it for gold, paid $40,000 cash for it. The property is undeveloped, but the purchaser proposes to open it up and work it on an extenaive scale.

Useful Information.

Formulas for Bronze Alloys.

Edward Kirke, iu writing nn the founding of alloys for the *Iron Age*, gives the following formnlas:

A bronze in imitation of gold may be made of 45.5 parts copper, 3.5 parts tiu and 1 part ziuc—50 parts.

Bronze metals are generally cast of an alloy of 50 parts copper and 2.8 parts tin. This alloy is very hard.

A softer bronze for medals than the above is composed of 46 parts copper and 4 parts tin.

Ancient bronze nails were made of 40 parts copper to 1 part tin, and were very flexible.

Soft brouzo is composed of 18 pounds copper to 2 pounds tin.

Hard bronze is composed of 20 pounds copper to 5 pounds tin.

The ancient brouze mirrors are said to have contained 16 parte copper to from 7 to 8 parts tiu.

At the time of Louis XIV of France, a period wheu the art of casting statues was much cultivated in France, statues were cast of an alloy of 30.6 parts copper, 0.11 parts tin, 2 parts zinc and 0.6 parts lead.

The statue of Louis XV is cast of 82.4 parts copper, 10.3 parts zinc, 4 parts tin and 3.2 parte lead.

The bronze of the ancient Greeks consisted chiefly of copper and tin, but was frequently alloyed with arsenic, zinc, gold, eilver aud lead. All their ehields and weapons of war were made of bronze, as well as coin, nails, kitchen utensils, etc.

All the ancient nations seem to have understood the art of tempering hronze and copper, and the Mexicans understood the art of converting hronze into edged instruments in a high degree, but the art of tempering and hardening bronze and copper has heen lost to modern nations; hut as we understand the working of iron hetter than the ancients, and have steel, an alloy of iron and carhon, which the ancieuts did not have, we do not miss thie art much.

Patent Flour.—Almost everybody knows of the flour, says an exchange, but not every one uuderstands what it is. Stripped of technicalities, this is perhaps the etory of its manufacture. The hest flour used to he made of winter wheat. Spring wheat yielded either much less in quantity, or else so much of the hran got into the flour in its maufacture that its color was intolerahly dark. The wheat would be ground and then holted. In the refuss—the hran aud middlings—would he included a large portion of the weight of the spring wheat, and this would sell more particularly for feed for horses. Now the hest of flour, and the most expensive, is made of this very refuse of the old-fashioned process. It all came out of the discovery of a way to draw out the bran. Under the new process the wheat is ground about as before. The first result is an ordinary flour sold for exportation. Then the remainder is taken and put upon great horizontal sieves, and, while agitation is going on there, an ingenious system of draft rushing up through carries off the hran. What is left is the glutinous portion of the wheat, the most nutritious and most productive, and out of this, purified now hy the drawing off of the bran, we get our new-process flour. The result of the discovery of the precess has been to make the poor epring wheat of Minnesota and upper Wisconsin the most valuable kind of grain, and to make the fortunes of the inventors of the method.

A Substitute for Tower Clocks.—Reiniger, of Stuttgart, proposes an ingenious substitute for illuminated tower clocks. It is no more or less than the use of a magic lantern, sometimes employed for etreet advertising in this country. A small lantern could he so arranged as to throw the picture of a common watch or chronometer upen a suitable white screen in places much frequented at night. The movements of the hands would he quite as distinct as those of a real clock with a transparent face and strong light behind it; while it would have the advantage over many of these that the axis to which the hands are attached would not throw a shadow often mistaken for one of the hands themselves. The project recommends itself to smaller cities unable to bear the expense of a costly tower clock with illuminated face.

Cement.—In stopping holes in castings, or for covering scars; a cement may be made of equal parts of gum arabic, plaster of paris and iron filings, and if a little finely pulverized white glass he added to the mixture, it will make it still harder. This mixture forms a very hard cement that will resist the action of fire and water. It should be kept in its dry state and mixed with a little water when wanted for use. A cement for making joints in water and steamp pipe, or in any work where two pieces of metal are joined together and it is desirable to make a perfectly tight joint, may he used, made of iron filings or turnings mixed with sal-ammonia. The proportions of sal-ammonia is very small; only about a half pound is used to 50 pounds of filings. This cement is mixed when wanted for use, and is driven into the joint with a cold chisel or other tool.

Anti-Fungus Paint.—The *Thon-Industrie Zeitung* states that a M. Reissig has patented a paint for walls, ceilings and the like, that renders the penetration of fluids or vapors impossible and prevents the formation of fungi, and is of such stability that it can be washed down with boiling water without injury. This paint or varnish is, essentially, a solution of stearate of soda in spirit, in the proportion nf about 50 grammes of the stearate to 1,000 of sp. gr. 66. Spirituous solutious of seap of all kinds and strengths can bs applied in a similar manner, but where cost is no particular object, the stearate of soda is far to he preferred, as it forms a very hard and firm coat, which can be thoroughly cleaused without the application of moisture. The solution may be tinted as desired with dragon's blood, auiline dyes, etc., or by the direct admixture of ordinary colors that are not subject to decomposition, such as ocher, ultramarine and the like. The paints are said to present an especially handsome appearance, and in the sick wards of hospitals, or in cattle sheds where disease is prevalent, can readily he mixed with disinfecting materials. They do not readily adhere over oil paint, but lie well on wood, plaster and cement.

A Paste that will Keep Well.—A correspondent gives an exchange this formula for a non-poisonous paste that will keep well in hot weather:

Wheat flour	1 ounce.
Powdered alum	½ drachm.
Water, sufficient, or	8 ounces.
Oil of clove, or wintergreen	3 or 4 drops.

Ruh the flour and the alum with the water to the consistency of milk; place this over a moderate fire, and stir constantly, until the paste drops from the wooden paddle in jelly-like flakes, and has the appearance of glycerite of starch. While the mass is still hot, add the csseutial oil, and pour the paste into an earthenware pot or open jar. In the course of ahout au hour a crust forms on the top; pour gently on this an inch of water, more or less. When some paste is wanted, decant the water, take out the quantity needed, and put some water again on the remainder, repeating the operatien each time. Paste may he kept in this way for months, and will never he trouhled with flies.

Postage-Stamp Mucilage.—The following is said to he the formula for the mucilage used on the United States postage-stamps: Dextrine, 2 oz.; acetic acid, 1 oz.; water, 5 oz.; alcohol, 1 oz. Add the alcobol to the other ingredients, when the dextrine is completely dissolved.

Good Health.

Notes on Consumption.

Dr. Geo. H. Napheys, an eminent physician, says: A particular kind of exercise is to he recommended for those whose chests are narrow, whose shoulders stoop, and who have a hereditary predisposition to consumption. If it is systematically practiced along with other means of health, we would guarantee any child—no matter how many relatives have died of this disease—against its invasion. It is voluntary inspiration. Nothing is more simple. Let her stand erect, throw her shoulders hack, and the hands hehind; then let her inhale pure air to the full capacity of her lungs, and retain it a few seconds by an increased effort; then it may he slowly exhaled. After one or two natural inspirations let her repeat the act, and so on for 10 or 15 minutes, twice daily. Not only is this simple procedure a safeguard against consumption, hut, in the opinion of some learned physicians, it can cure it when it has already commenced.

A correspondent of an English medical journal furnishes the following recipe as a new cure for consumption: Put a dozen whole lemons in cold water and hoil until soft (not too soft), roll and squeeze until the juice is all extracted, sweeten the juice enough to he palatahle, and then drink. Use as many as a dozen a day. Should they cause pain or looseness of the bowels, lessen the quantity and use five or six a day until hetter. By the time you have used five or six dozen you will hegin to gain strength and have an appetite. Of course as you get hetter you need not use so many. Follow these directions and we know that you will never regret it if there is any help for you. Only keep it up faithfully. We know of two cases where hoth of the patients were given up hy the physicians, and were in the last stages of consumption, yet both were cured by using lemons, according to the directions we have stated. One lady in particular was hedridden and very low; had procured everything that money could procure, hut all in vain, when, to please a friend, she was finally persuaded to use the lemons. She hegan to use them in February, and in April she weighed 140 pounds. She is a well woman to-day, and likely to live as long as any of us.

An Anecdote of Jenner.—The celebrated Dr. Jenner, who introduced vaccination, was a man of genial wit, and the following lines addressed to a lady upon the recovery of her daughter, and sent with a pair of ducks, afford a fair specimen of his facetious vein:

"I've dispatched, my dear madam, this scrap of a letter,
To say that Miss ——— is very much better;
A regular doctor no longer she lacks,
And therefore I've sent her a couple of Quacks."

Dieting for Health.

Dieting for health, says *Hall's Journal*, has sent many a one to ths grave, and will send many more, because it is dons injudiciously or ignorantly. Ons man omits his dinner hy a herculean effort, and thinking he has accomplished wonders, sxpects wonderful results, hut by the time supper is ready he feels hungry as a dog, aud eats like one, fast, furious and long. Next day hs is worse, and "don't believe in dieting" for the remainder of his life.

Others set out to starve themselves into health, until the system is reduced so low that it has no power of resuscitation, aud the man dies.

To diet wisely, does not imply a total abstinence from all food, but the taking of just enough, or of a quality adapted to the nature of the case. Loose bowels weaken very rapidly—total abstinence from all food increases the debility. In this case food should be taken, which while it tends to arrest the disease, imparts nutriment and strength to the system. In this case, rest on a hed, and eating boiled rice, after it has heen parched like coffee, will cure three cases out of four of common diarrhœa in a day or two.

Others think that in order to diet effectually, it is all important to do without meat, hut allow themselves the widest liherty in all else. But in many cases, in dyspeptic conditions of the system particularly, the course ought to he reversed, hecanse meat is converted into nutriment with the expenditure of less stomach power than vegetables, while a given amount of work does three times as much good, gives three times ae much nutriment and strength as vegetable food would.

Atomized Sea-Water in Bronchial Diseases.—Prof. Mantegazza, in an Italian medical journal, as translated by the *Journal of Chemistry*, states that he has derived great advantage from the employment of pulverized or atomized sea-water in cases of chronic non-specific laryngitis, obstiuate chronic pharyngitis, bronchial catarrh, from chronic bronchitis with or without bronchial dilatation, the first and second stages of pbthisis, caseous pneumonia, and chronic pneumonia of different forms accompanied hy profuse hronchial expectoration, and various forms of scrofula. He does not advise it in those forms of phthisis which pursue a rapid course and are accompanied hy much febrile action and great hronchial irritation. In all doubtful cases trials may he made of a few inhalations, which, if they do no good, do little or no harm. Pulverizations of sea-water are now executed at several establishments in Italy, especially at Rimini, where they are conducted on so large a scale that 20 persons may receive them at the same time, the pulverization heing effected hy means of compressed air and a steam engine. The administration lasts for half an hour at first, and afterwards for an hour, from 30 to 40 of these being required. The patients while respiring the vapor should he encouraged tn talk and sing as far as their strength allows. The first effects produced are a pleasant excitement and a return of appetite.

Beef Tea.—Prof. Pepper, in a lecture on typheid fever, in the Philadelphia *Medical Times*, observes: "Indeed, as has been very thoroughly proven by Dr. Horace Hare in experiments made at the University laberatory, heef hoiled in the good old-fashioned way in a hottle with water gives us a resulting eolution which contains only ahout one-fourth of one per cent. of nourishing material. The heef tea thus manufactured is chiefly a solution of the salts of meat, and is, therefore, not nutritive, and only valuable as a stimulant to digestion. But there is another way of making heef tea which gives hetter results. Take a quantity of tender meat, and, after cutting off the fat, chop it up fine, put it in a bowl, pour a pint of water over it, and let it stand over night. It may possihly he well to keep the water just on a simmer; do not raise the temperature above 140°, however, or you will coagulate all the alhumen, and so either leave it on the sieve in straining, or introduce it into the stomach in the form of curds. After this simmering solution has heen allowed to stand over uight, pour it into a pipkin and heat it again gently, with enough salt to give it flavor, and, if necessary, add a drop or two of muriatic acid. Then pour it out over a hair sieve into a jar. The resulting solution will contain all the nutriments possihle, and is the most valuable kind of stimulant and laxative.

Effects of Perfume on Health.—An Italian professor has made some very agreeahle medicinal researches, resulting in the discevery that vegetahle perfumes exercise a positively healthful influence ou the atmosphere, converting its oxygen into ozone, and thus increasing its oxidiziug influence. The essences found to develop the largest quantity of ozone are those of cherry, laurel, clover, lavender, mint, juniper, lemon, fennel and hergamot; those that give it in smaller quantity are anise, nutmeg and thyme. The flowers of the narcissus, hyacinth, mignonette, heliotrope and lily of the valley develop ozone in closed vessels. Flowers destitute of perfume do not develop it, and those which have but slight perfume develop it in small quantities. Reasoning from these facts the professor recommends the cultivation of flowere in marshy districts, and in all places infested with animal emanations, on account of powerful oxidizing influence of ozone.

The Week.

Spared the sun storms that are prostrating so many people at the East as well as the communism and tramp element there so fearfully developed, the residents of California feel that they have reason to congratulate themselves on their good fortune. Then, too, most of our national interests are in a prosperous condition. The demand for harvest and dairy hands was never better than at present, the demand having pretty well absorbed the surplus labor of the cities. The wages paid for this sort of service are liberal, considering the low prices of farm produce and the general dullness of the times. Where employed by the month this class of laborers receive from $25 to $30, day hands receiving from $1.50 to $2, with keep in all cases. There are fewer Chinamen being employed in the grain harvest this year than usual, as they do not here form a desirable kind of help, and there are plenty of white men to be had. The disposition shown by some of our large California landholders to subdivide their possessions into small tracts and sell them on easy terms is considered a move in the right direction, and if carried out will lead to very salutary results all round. Some of our land kings have already taken preliminary steps looking to the early breaking up of their unwieldy, and, at present, profitless estates.

Nothing determinate has yet been achieved in the Indian war raging on our northern borders, though our troops have at last succeeded in getting the savages pretty well surrounded. All efforts to get them so hemmed in as to force them to a general engagement have thus far been defeated, the wily foe, when sorely pressed, retreating, and when at last nearly surrounded, breaking up into small bands, the most of which manage to elude pursuit.

Records of the Stetefeldt Furnace.—No. 2.

Furnaces Erected and Results Obtained.

There have been erected since 1869, altogether 22 of these furnaces in the United States. A great many of them are now idle, the mines having failed to supply ore. The most notable furnaces have been erected in the following places:

Manhattan Mill, Austin, Nevada.

This furnace has been in operation since August, 1870, and has roasted to the end of May, 1878, over 40,000 tons of silver ore with chloridation, averaging from 90% to 91%. The ore of Reese River district contains antimonial sulphurets of silver, zinchlende, galena and pyrites of iron and copper.

Mineral Hill Mill, Mineral Hill, Nevada.

This furnace has been in operation for two years only, 1871 and 1872, during which time it roasted abont 9,000 tons of ore, with average chloridation of 90% to 92%. The silver-bearing mineral was mostly stetefeldite.

Surprise Valley Mill, Panamint, Cal.

The furnace at this mill, built in 1875, had, under Mr. Weberling's superintendence, only a short but very successful run, roasting about 5,000 tons of ore with chloridations, averaging from 92% to 93%. The silver-bearing mineral was mainly silver-fahl ore, with some zinchlende, iron and copper pyrites, and galena.

Northern Belle Mills, Columbus District, Nev.

The furnaces at the Northern Belle were erected, one in 1875 and a second in 1876. They have a most remarkable record to show. Each of these furnaces has a capacity of 50 to 60 tons in 24 hours, and as much as 70 tons have been put through one of them occasionally. Up to the end of May 1878, these furnaces had roasted 65,000 tons of ore, with an average chloridations of 91 7-10%. These statistics are from the Superintendeut, Mr. Wm. F. Belding. The ore is mostly oxidized and contains a large percentage of the hydrates of the oxides of iron and mangancse. But there occur, also, heavy sulphurets of the base metals.

Ontario Mill, Park City, Utah.

A Stetefeldt furnace was put in operation at the Ontario mill in February, 1877. The Ontario mine carried in its upper levels a great amount of decomposed ore, which yielded a very high percentage of its silver by raw amalgamation. In the lower levels, however, the character of the ore changed entirely and the ore from this part of the miue can he successfully amalgamated only by first roasting it with salt. After reaching the 500 level, the ore became much baser than that met with before, and as the working of the furnace gave occasionally results much inferior to those formerly obtained, an analytical investigation was ordered.

Specimens from the 500 level of the Ontario plainly show the following minerals, viz: Zinchlende, galena, fahl-ore, and iron pyrites. Of the zinchlende there are two varieties, the one of a light yellow color, the other black. In the latter a larger quantity of fahl-ore is found between the cleavage planes than in the former. The galena also often occurs intimately mixed with the fahl-ore. The fahl-ore itself occurs besides in compact masses.

A chemical analysis of an average sample of crushed ore from the 500 level of the Ontario mine gave the following results, viz:

One hundred parts of the ore contain:

Zinc	9.60
Lead	6.07
Iron	2.77
Copper	1.41
Manganese	0.45
Silver	0.60
Sulphur	7.68
Antimony	1.20
Arsenic	0.20
Silica	55.21
Alumina	13.14
Potash and soda from decomposed felspathic matter	1.00

Traces of bismuth, cadmium, lime and magnesia. Assay value, $229.34 silver per ton.

The differeut minerals were separated as well as their small difference in specific gravity allowed, and were found to he composed as follows:

Yellow zinchlende contains:

Iron	1.60 per cent.
Copper	0.40 " "
Cadmium	Trace.

Assay valne $92.50 silver per ton.

Black zinchlende contains:

Iron	2.40 per cent.
Copper	0.84 " "
Cadmium	Trace.

Assay valne, $92.50 silver per ton.

Galena contains:

Iron	1.80 per cent.
Copper	0.06 " "
Bismuth	Trace.

Assay value, $175 silvor per ton.

Fahl-ore contains:

Copper	24.16 per cent.
Silver	11.77 " "
Zinc	6.70 " "
Lead	4.20 " "
Antimony	27.00 " "
Arsenic	4.40 " "
Sulphur	22.20 " "

Assay value, $4,440 silver per ton.

Taking these results as a basis, we find the ore from the 500 level of the Ontario to he composed as follows:

15.00% zinchlende with $13.87 or 6.0% of the silver.
7.60% galena with $13.30 or 5.8% of the silver.
4.55% fahl-ore with $202.17 or 88.2% of the silver.
3.50% iron pyrites and metallic oxide, with a trace of silver.
60.35% gangue composed of quartz and clay.

This proves conclusively that the fahl-ore is the main source of the silver in the Ontario ore. It is, of course, more or less intimately mixed with the galena and zinchlende, but in crushing the ore through a No. 60 screen the fahl-ore becomes sufficiently exposed to allow its roasting independently of the minerals with which it is associated.

Ore, of exactly the same character as that analyzed, was roasted with about 13% of pure salt in the Stetefeldt furnace, and samples taken from the shaft and flue. These were subjected to a chemical analysis. The object of this investigation was to ascertain:

1. If there is a sufficient quantity of salt falling down the shaft, or if the low results were due to a deficiency in that direction.

2. If undecomposed salt is left in the roasted ore, and how much.

3. Which of the metals have been changed to chlorides, and which to sulphates.

4. How much unoxidized sulphur has been left in combination with metals as sulphurets.

The solution of these questions must give an exact knowledge of the working of the furnace.

Without going into the details of the analysis, which we have inspected and find very carefully made, we give the final results.

The sample of roasted ore from the shaft was found to contain in 100 parts—

Chloride of copper	0.25
Chloride of aluminum	1.51
Chloride of zinc	1.38
Chloride of sodium	3.63
Other chlorides	traces
Sulphate of lead	3.26
Sulphate of alumina	0.56
Sulphide of soda	4.02
Other sulphates	traces
Metallic oxides, gangue, etc	rest

Of the silver contained in the ore, 81.32% was chloridized. Sulphur in undecomposed sulphurets, 0.18%.

The sample of roasted ore from the flue was found to contain in 100 parts—

Chloride of aluminum	1.07
Chloride of sodium	3.08
Other chlorides	traces
Sulphate of copper	0.74
Sulphate of alumina	2.88
Sulphate of zinc	1.48
Sulphate of lead	5.18
Sulphate of soda	10.01
Other sulphates	traces
Metallic oxides and gangue	rest

Of the silver contained in the ore, 82.24% was chloridized. Sulphur in undecomposed sulphurets, 0.064%.

These very interesting results prove:

1. That in the shaft as well as in the flue over 3% of undecomposed salt are present; and that consequently an increase in the amount of salt used in roasting would be useless.

2. That there remains more undecomposed salt in the shaft than in the flue, and that the low results lately obtained in the chloridation of the silver cannot be accounted for by an insufficient amount of salt dropping down the shaft. Consequently it would be of no benefit to crush the salt by itself through coarser screens.

3. That the volatilization of the salt is by no means as great as supposed.

4. A peculiar relation exists between the shaft and flue with regard to the salts of copper, zinc and aluminum. Copper and zinc are present in the shaft only as chlorides, in the flue only as sulphates. The aluminum exists in the shaft as well as in the flue in both combinations, but in the shaft the chloride predominates, in the flue the sulphate. It is evident that in the shaft the metallic sulphates are more completely decomposed, as the ore falling against the rising gases is no longer suspended in the heat, and passes finally through the hottest zone of the furnace. In the flue the ore particles moving with the gases are only for a moment exposed to the flame of the auxiliary fireplace, and being instantly transferred to a lower temperature, the sulphates are formed, have no occasion to leave their acid, except by contact in the change with salt, which is necessarily a slow and imperfect mode of decomposition. The presence of these sulphates has, however, a beneficial effect upon a further chloridation of the silver in the ore at the bottom of the flue.

As to the lead, we find it only as a sulphate in the shaft as in the flue, but the preponderence of the formation of sulphates in the flue becomes again evident. As the sulphate of lead cannot lose its acid at a high temperature, it follows that its decomposition in the shaft cannot be accomplished.

5. The complete oxidation of the sulphur is very surprising, and shows how thoroughly the furnace does its work with such base ores.

6. Chloridations of 81% and 82% of the silver are very high for Ontario ore, and with such chloridations from 90% to 94% of the silver are extracted by amalgamation without any difficulty.

The results of this investigation have clearly demonstrated that ores as those from the 500 level of the Ontario can he worked with perfect success by this furnace, if proper conditions are maintained. Inferior results were only caused by a deficiency in the draft of the furnace, or in overfeeding it when the draft was not in a normal condition. These were defects easily corrected.

The following is a statement of the working results obtained at the Ontario mill, furnished by Mr. C. M. Watkis, the metallurgist of the mill.

The Stetefeldt furnace has roasted from February, 1877, to the end of May, 1878, 10,500 tons of ore. The following average results were obtained by amalgamation in pans:

Month. 1877.	Value of battery sample after deducting salt.	Value of tailings from settlers.	Per cent. remaining in tailings.
July	$139 00	$17 12	12.3
August	120 00	12 22	10.2
September	141 83	13 92	9.8
October	142 40	9 70	6.8
November	134 72	8 08	6.0
December	140 45	9 50	6.8
1878.			
January	139 40	14 40	10.3
February	155 20	30 50	19.6
March	152 61	17 57	11.5
April	152 40	20 82	17.6

These results were obtained with comparatively low chloridations, which have rarely exceeded 90%, and, since the 500 level was reached in January, 1878, have been occasionally as low as 50% in the shaft for reasons stated above. As soon as the draft of the furnace is corrected, the same good results will be again uniformly obtained.

Royalties, Etc.

The royalties charged hy the Stetefeldt furnace company, have been reduced to $1 per ton on ores above $50 assay value, and to 50 cents per ton on ores of a lower grade. They also sell outright the right to exclusive use of the furnace in certain districts. The terms of such sale vary with districts, capacity of furnace, etc. For further particulars we refer to Mr. C. A. Stetefeldt, room 61, No. 320 Sansome street, San Francisco, Cal.

A New Cement Mill.

We examined, this week, at Prescott, Scott & Co.'s, a ponderous piece of machinery for crushing cement, which has been built for the New York & Calaveras mining company. The machine weighs 124,000 pounds, is 41 feet long and six and a half feet in diameter. It consists of a large cylinder, set on an incline of half an inch to the foot and arranged to revolve, similar to the Bruckner furnace cylinder. The cylinder is composed of T-iron, the flanges of the rail projecting inwards, so as to form corrugations on the inside. In that half of the cylinder nearest the feed end, the T-iron bars are set close together, so that the cylinder is tight. The other half has the iron set so as to leave spaces between the rails to allow the crushed cement to pass through the interstices into the sluice, over which the cylinder is placed.

It is arranged to rotate on three sets of wheels, and is kept in position, being on an incline, by means of a brace, also carrying small wheels, pressing against a ring attached to one end of the cylinder. The power is furnished by a 14x24 engine, and boiler, 48 inches by 16 feet. The power is conveyed by the engine to the cylinder through a gear and pinion, connection being broken at pleasure by means of a clutch. The engine is geared to the center of the cylinder.

This machine is intended to work 60 tons of cement an hour. The ore is fed into the upper end with water enough to moisten the substance. A perforated pipe passes through the cylinders through which jets of water play on the cement as the cylinder is revolved. The sand, dirt, etc., is thus washed off the boulders and passes out of quarter-inch spaces into the sluice, while the boulders pass out of the lower end of the cylinder. The intention is to place the machine in a position where the boulders, etc., will pass out over a bank or place where there is dump room. It is more particularly intended for making auriferous cement, and low-grade material of a similar character which cannot be worked hy hydraulic. The action of the flanges in the cylinders is such as to break or grind up the pieces, and the water assists in washing off the sand, etc., from the boulders. Two smaller machine have been worked for some little time with great success. It is claimed that with plenty of dirt it can he worked at a profit on material worth only 25 cents per ton. They will be able, with these machines, to utilize a great deal of ground now lying idle. Water is allowed to enter the cylinder with the cement in proportions suitable to the class of material being worked.

SIERRA FLUME AND LUMBER COMPANY.—We regret to announce that this large lumbering association has been compelled to suspend operations and assign its property. A dispatch from Chico says: The Company publish a card this afternoon in the *Record*, announcing that all the workingmen engaged hy them who have preferred claims to the amount of $100 for services, will be paid promptly hy the assignees. Many of the hands have sold their claims already for 60 or 70 cents on the dollar. The general opinion is gaining ground that the mills will not he started up again this season, hut there are several million feet of lumber already cut which will be flumed down to the dumps at Chico and Red Bluff before the close of the lumber season.

THE cars are now running between Martinez and Oakland. Work on the section between Martinez and Antioch is progressing favorably, with every prospect that the line will be in operation for the overland and southern California business within the period of 60 days.

The Cerro de Pasco Mines.

A Description of the Mines and the Machinery Recently Shipped There.

There was shipped this week from this city on a vessel chartered for the purpose, a complete 80-stamp mill with all modern appliances, intended for use at the famous Cerro de Pasco mines in Peru. These mines have recently come into the hands of a company who intend working them systematically, so as to fully develop the immense property in a manner commensurate with its worth. Borings have been made at various points with diamond drills, the results of which have been eminently satisfactory. Large Cornish pumps have also been put at work to drain those portions of the mines not drained by the tunnel, but outside of the pumps and drills no modern machinery has been introduced at Cerro de Pasco. The new 80-stamp mill, however, when it gets at work will probably do as much work in a week as was previously accomplished by patio process at all the haciendas put together, in a year.

Before giving the brief description of the mines which we propose, it will be of interest to give the details of construction of the new 80-stamp mill, since the work is one which reflects credit on San Francisco mechanics, and was finished in a remarkably short space of time.

The New 80-Stamp Mill.

It was built by Rankin, Brayton & Co., of the Pacific Iron Works, on an order from Mr. W. H. Cilley, General Superintendent of the Oroya and Cerro de Pasco railroad and mining company, who is at present in this city. The building in which the mill is to be placed is to be 290 feet long with an average width of 110 feet. It is to be set on a side hill so that the machinery may be arranged to save handling of the ore. The outside walls are to be made of stone, and Mr. L. S. Carr, well known as a millright on this coast, has already gone to Peru to see to the construction of building and mill.

The ore is brought from the mines by railroad and the cars are drawn by the locomotive into the ore house. The ore is dumped on to "grizzlies," of which there are six. That which is fine enough to pass through between the bars goes directly into the hoppers or bins. That which is too large is directed to platforms in which there are Blake ore crushers and thence to the bins. There are four of these crushers, 7x9. There are two large bins so that the two run the length of the building. From the bins the ore is drawn off into 16 Hendy ore feeders, which feed it into the batteries. From the batteries it runs by spouts to the settling tanks. It is then shoveled on to the sand floor and into the amalgamating pans, thence to the settlers and afterwards to the agitators. The sand that settles in the agitators is shoveled up to a floor and reground in four grinding pans, six feet in diameter. The quicksilver is not handled at all. It is pumped by two of Boss' quicksilver pumps into tanks, and runs into the pans and settlers and then into bowls from which it is pumped back again.

There are in all 40 amalgamating pans, 20 settlers, four agitators, four grinding and four clean-up pans. Also two quicksilver pumps and two quicksilver presses, the latter for straining amalgam.

The Turbine Wheels.

The power to drive this machinery is derived from water, no steam being used. There are four Leffel turbine wheels for driving the pans, each 30½ inches in diameter; two 23-inch Leffel turbines drive the batteries. These wheels run with a head of 45 feet. The battery turbines will run 400 revolutions and the pan wheels 300 revolutions per minute. The water is brought in from each end of the building through a 66-inch pipe. There are three of the turbines on each side of the mill, the center one on each side being for the batteries. The battery wheels are belted to a counter shaft to reduce the revolutions and from there to the battery line shaft, a separate pulley being provided for each set of five stamps. The other two turbines on each side, belt direct to the pan line. The pans and settlers are divided into two sections on each side, each section having ten pans and five settlers, an agitator and a grinding pan. In addition the two center sections have a grinding pan with two clean-up pans.

All of the machinery had to be made in sections for transportation on mules, and no piece could weigh over 300 pounds, which of course has added to the difficulty of construction. The cam shafts are split lengthwise so as to form two pieces accurately fitted and tongued and grooved. They are eight feet long. The stamp stems are 13 feet long and 3⅜ inches in diameter. The battery line shafting is cut in short lengths the largest diameter being 4½ inches. This shafting is driven by a wooden 84-inch pulley with 23-inch face. The mortars, it may be stated, are to be cast at the mines, the core boxes having been made here. This was necessary as the weight would have greatly exceeded the limit.

The Pans, Settlers, Etc.

The pans are the "combination" pans, 62 inches in diameter inside and 30 inches high. The pan bottoms, 1½ inches thick, are made in six pieces with the joints all planed and fitted with bolts so as to be interchangable. The sides are made in six pieces three-fourths of an inch thick, all planed and bolted together so as to be interchangable. The upright shaft for driving pans is 4 inches in diameter and 7 feet long. The pans are made to run 90 revolutions, geared two to one. Each pan has eight shoes and six dies. The joints are all turned and planed.

The settlers are nine feet in diameter and 30 inches deep with sheet-iron sides; bottoms are made in ten pieces. Each settler has attached four cast-iron arms with two shoes to each arm. The joints and faces of bottom are planed and fitted to be interchangable. The main upright driving shaft is 3¼ inches in diameter and six feet three inches long. The settlers will make 15 revolutions, geared four to one.

The settlers are driven from the main settler line of shafting by a clutch instead of the usual tight and loose pulleys. This line is driven from the pan line shaft by a 16-inch belt. Below each settler is a quicksilver bowl, from which the mercury is pumped back to the receiving tanks.

The agitators are of wood, nine feet in diameter and 36 inches deep. The sides are three inches thick and the bottom four inches. The arms are of cast-iron, the four arms being each fitted with six cast-iron teeth 21 inches long. These agitators are to run 20 revolutions, geared four to one, driven by tight and loose pulleys from settler line.

The four grinding pans are six feet in diameter and 24 inches deep; will run 25 revolutions geared two to one. The sides are made of six pieces of sheet iron. These will be driven from the settler line of shafting. The clean-up pans are five feet in diameter and 18 inches deep, made in four sections.

Weight, Etc., of the Machinery.

All this machinery, as stated, is made in pieces of less than 300 pounds for convenience of transportation. The whole weight aggregates 530 tons, and the machinery was completed in 50 working days from receipt of order, during which time drawings and all were made. The general plans, which are excellently executed, were drawn by Mr. J. K. Firth, draftsman at the Pacific Works, and the details were drawn by Mr. Erlach. Mr. Cilley visited Virginia City before ordering the mill, in order to see the various improvements in milling machinery. There are only four 80-stamp mills on this coast, none of which, however, were originally constructed with that number of stamps. The stamps for the mill weigh 870 pounds, being a little heavier than customary.

The work is all well finished and no expense has been spared to make the mill perfect in all its parts. The capacity is from 350 to 450 tons per day. A Howell roasting furnace has been shipped with the mill, but is for experimental purposes only.

The Superintendent of the Mill.

We are pleased to state, in this connection, that Mr. Cilley has appointed as Superintendent of the mill, Mr. A. D. Hodges, formerly editor of this journal and more recently connected with the milling interests at Dayton, Nev. No better choice could have been made, Mr. Hodges being a young man of great intelligence and ability, a thorough metallurgist and an enthusiast in his profession. Being a good chemist, a practical mill man and close student, Mr. Hodges will, without doubt, be able to work the ore as close as it is possible to do it and at the same time in an economical manner.

Cerro de Pasco Mining District.

The mines to which this machinery are to go are famous in the world's history. They lie in the province of Junin, Peru, at an elevation of 14,000 feet, and were discovered as long ago as the year 1630, and have been worked in a primitive manner, on a small scale, almost uninterruptedly ever since. There are two distinct veins, on which the principal work was done for many years, one running in a northeast and the other a northwesterly direction. These veins join in an immense mass or deposit of ore, the scene of present mining operations. The veins have been worked comparatively little since the discovery of this ore body, in the year 1630 all attention then being turned to that spot. The ore body of Cerro de Pasco is about a mile and a half long and nearly a mile wide, and it is this tract which the company, who have built this mill, are working.

The Product of the Mines.

The veins as stated, have been worked hundreds of years, and this body since its discovery. The mining, however, has been done in the most primitive manner, and no work has been accomplished below the water line. On reaching water, work was abandoned and new shafts sunk. The miners delved through the mass in search for rich pockets, the poorer ore being left. The pockets frequently found yielded enormously in born or native silver, and the whole tract has been "coyoted" in search of them. The ore below the water line is richer than above, as assays from diamond drill borings prove, but little of it has been worked as yet. The Peruvian miners brought up the water, as the ore, in leather sacks, and when too much water came in, their holes had to be abandoned. The deposit therefore, in all its magnitude is hardly touched, and would be considered scarcely prospected in a mining country like this. Nevertheless, the government records prove that upwards of $493,000,000 were produced for 1630 to 1821 by the Cerro de Pasco mines, and since that time about $3,000,000 a year has been produced, even by the primitive methods of mining referred to. Previous to 1821 it was obligatory on all persons to bring their metal to one place to be melted, in order that the tax might be collected, and probably a large amount was smuggled, of which no record could be made. At the time of the war of independence the mines were almost entirely abandoned and the haciendas allowed to go to ruin. About three-quarters of all the haciendas worked during the Spanish rule, have been abandoned since the war of the revolution. No capital has ever been invested, and the poorer ores have not been worked. The only reason so much money was taken out was on account of the presence of so many very rich pockets.

From 1828 to 1846 there were 4,647,052 marks (about $10 to a mark), produced, according to the best authorities. The mines were generally owned by Indians, who, naturally suspicious of one another, would allow no combinations to be made for work on a large scale. Each worked his little claim as he chose until he got to water, when he abandoned it and took another. The deepest shaft on the property is 360 feet deep, and has been sunk through the decomposed rock forming the surface ore. At the time the property was taken hold of by Mr. Henry Meiggs, there were only 53 claims of 90 by 60 varas, being worked by private individuals, all the remainder having reverted to the Government by a law which provides that those claims abandoned for four months become again government property. These mines came under the proprietorship of the present company in the following manner:

Mr. Meiggs' Contracts with the Peruvian Government.

Everybody has heard of the enormous interests acquired by Mr. Henry Meiggs in Peru, and of the magnitude of the contracts made by that gentleman with the government. His enterprise and skill accomplished objects which appeared almost impossible, and in railroad construction in particular he has astonished the engineers of the world. It is not our purpose to speak at length of these various enterprises, but to confine ourselves to Mr. Meiggs' connection with the Cerro de Pasco mines alone.

The Callao, Lima and Oroya railroad was built by the government, and Mr. Meiggs by contract took the road by administration, and for this administration was to receive five per cent. of the gross receipts.

This road ran within 85 miles of the Cerro de Pasco mines, and Mr. Meiggs directed the attention of the government to these mines from which so much money had been taken, but which were now practically abandoned. Negotiations were entered into for building a railroad to the mines, running a tunnel to drain them deeper, and developing their wealth. In order to accomplish this the government authorized Mr. Meiggs, or any representative of his, to issue bonds for £2,400,000 sterling for the construction of the Oroyo and Cerro de Pasco railroad and completing the tunnel. These bonds bore seven per cent. gold interest and were guaranteed by the Peruvian government. The security for paying principal and interest were placed at Mr. Meiggs' disposal. First, 200,000 tons of guano; second, the export duty of five per cent. on all treasure shipped from the country; third, the government profits on the railroad; and fourth, the government share of the profits from working the mines of Cerro de Pasco. All these revenues were to be applied to paying interest on the bonds and a certain specified excess to be used in funding them.

The mineral lands of Cerro de Pasco were therefore ceded to Mr. Meiggs under this contract, only 53 private claims being in existence at the time, as stated previously. These miners were given the choice of paying Mr. Meiggs 25% of the net yield of their claims in consideration of his driving the tunnel to drain the mines, or they could allow him to work their claims and pay them 30% of the net yield for the privilege. They all agreed to the latter proposition, so the whole property came into his hands. The government is to receive 25% of the profit of the mines after the bonds referred to are redeemed, but the remainder of the proceeds go to the company working the mines.

This cession was made to Mr. Meiggs in February 3d, 1877. The Cerro de Paseo railroad, which connects with the Callao, Lima & Oroya railroad, will be 85 miles long and will connect at Oroya. With the exception of 10 miles, it is on a level plateau and can be built in six months. There was previously a railroad of seven miles in length, which was built by an English company, which eventually failed, and the road was bought by Mr. Meiggs from the government, to which it had reverted, for $500,000. It has since been extended six miles further, in order to take the ore from the mines to the river, where the 80-stamp mill is to be erected. Along the whole length of this short road are places where the ore is now being worked by patio process. In this contract with the government, it was specially provided that Mr. Meiggs might cede his rights to companies or individuals who would carry out the projects.

Formation of the New Company.

When Mr. Meiggs died, his will contained a clause, leaving all his contracts with the government in charge of a Directory, giving that Directory full power to carry out the contracts in the name of the estate, or to transfer them to other individuals or companies, as they thought proper. If these contracts had been carried out in the name of the estate it would have taken 20 years to settle it up, so the Directory thought it better to transfer the contracts to others, where satisfactory arrangements could be made. A company was formed, called the Oroya Railroad & Cerro de Paseo mining company, and this company purchased from the estate the contracts for the Callao, Lima & Oroya railroad, and the Oroya & Cerro de Paseo railrond, and the Cerro de Pasco mines. This company was formed with a capital of £3,000,000 sterling, over £1,000,000 in stock having been sold and the remainder belonging to the company. The company also, considering the bonds a good investment, took them up themselves.

Of this company, Mr. W. H. Cilley, who is now in this city, is General Superintendent. He has been associated with Mr. Meiggs for some 18 years, and has been chief engineer of different works for Mr. Meiggs during that time. Mr. Meiggs contracts with the government amounted at times to $190,000,000, and he employed over 37,000 men at one time. In operations of such magnitude, the work had to be organized under different heads, of which Mr. Cilley was one.

That portion of Peru about the Cerro de Pasco mines is all a rich mining country, after passing the summit, interspersed with agricultural tracts. There is an abundance of water power and plenty of salt near by. The salt which has supplied the mines for years is carried on wagons to the lake, there shipped on steam launches and sailing boats, carried to the other end of the lake and thence on mules to the mines.

The Ore Deposit.

The old tunnel which now drains the mines was built by the Spaniards during the Viec-Royalty. It was commenced in 1806 and finished in 1841, the work being done slowly. With its ramifications it is 3,440 meters in length, and drains the mines 297 feet below the surface at the deepest point. This tunnel now discharges about 79 miners' inches of water. The company have now two Cornish pumps, 37½ inch steam cylinder and seven-foot stroke, which pump water up to the old tunnel level, a pair of engines working each pump. Two more pumps are now ready for work, and it is thought the four will free the mines of water down to the new tunnel level.

The ground in the ore deposit is caved in all directions from the burrowing operations of the miners, some of these caves covering acres in extent. There are a large number of small shafts on the property, but the company is principally engaged in opening up open cuts. The property is all to be worked by open cuts, as they blast the ore down from the sides, shovel it on to cars and transport it to the mills. They are accumulating a large amount of ore now ready for milling, principally low grade, just as it comes out. The ore is all free milling down to water level, and there is an immense quantity of it. It changes at the water line and the higher grade ore is refractory.

Yield of the Ore.

The ore just as it comes from the mass or deposit will average $30 per ton, without taking rich pockets into consideration. Some 500 assays from diamond drill borings in deeper ore show an average yield of $165 per ton. It costs now for blasting, mining and loading on cars in the open cuts, ten cents per ton. There is no limit to the amount to be taken out, and as the cuts are extended and facilities improved, the ore can be more easily removed to the mills Mr. Cilley thinks if he had 20 mills like the one described above, he could keep them all running to full capacity. The company is at present working a number of the old haciendas which came to them, a portion by government cession and part by purchase. They have been repaired so as to work until machinery could be provided, but are principally valuable as giving exclusive water privileges to the company.

The New Tunnel.

The new tunnel being run by the company will drain the mines about 260 feet below the present water level, or 560 feet below the highest point on the surface. This tunnel will be from 1,700 to 1,800 meters in length before reaching the ore body, and how much further it will be run will depend on circumstances.

Where the mining is at present being done the tracks are run in on a level and the cars loaded from the sides of the cut by the Indians. They receive so much a ton for their work, one man being paid and he dividing it up in shares according to the number of men at work. They will not be able to get down into the richer ore for some time, as it will perhaps be two years before the lower deposits are available.

The company own large coal fields near the mines and will use the coal in working the mines and in the smelting furnaces. The new mill will be put up 13 miles from the mines at the end of the short railroad, where the water power is available.

It will be seen that this company has undertaken work of great magnitude, and is going about it in a systematic manner. It takes capital, however, to work mines in Peru, and no poor man need think of ever doing anything in that line there. Labor is procured for comparatively nothing, so to speak, a fortunate circumstance for large companies, but a bad one for working miners.

A Big Pump.—A. L. Fish & Co., Nos. 9 and 11 First street, have just received one of Knowles' plunger pumps, intended for the Empire coal mine. It is the largest one that ever came to this coast, and is well worthy of examination by mining men. The steam cylinder is 24 inches in diameter, water cylinder 10 inches in diameter. The total weight of the pump is nearly 10 tons. It is calculated to raise 25,000 gallons of water per hour 500 feet.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N.E.COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E corner Pine, S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.50.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

From A Patentee.

SAN FRANCISCO, July 1st, 1878.

MESSRS. DEWEY & CO., PATENT SOLICITORS.—*Gentlemen:*—On the first of June I made application for Letters Patent for an improvement on a fire-resisting and non-conducting compound through your Patent Agency, and was agreeably surprised to receive official notice that the patent had been allowed on the 15th day of June, in the unprecedented short time of fifteen days from the time it left here.

This is the seventh patent which I have procured through your Agency, entire satisfaction being given in each case, and I shall take great pleasure in recommending your firm for reliability and promptness to all inventors with whom I may come in contact.

I have now two more cases ready, and shall make the application through your Agency.

Yours Truly, GEO. R. EVANS.

Much Obliged, Etc.

PORTLAND, OREGON, June 26th, 1877.

DEWEY & CO., Patent Solicitors, S. F.—*Gents:* I am much obliged to you for courtesy shown me, and am much pleased with the manner in which you have done my business, and assure you, will cheerfully recommend you to my acquaintance needing such services. Hope to have a case again before long, of my own. I have been an inventor all my life, but let others reap the benefit, or had work taken from me. Please have the extra copies of my patent, etc., mailed to me direct, and oblige

Yours truly, J. H. WOODRUM.

WRITING ON BOTH SIDES.—A correspondent asks about writing communications on both sides of the paper. It is always a source of more or less inconvenience to do so. If the article is on the same subject, but one type-setter can work at it at once, and it is often desirable to divide an article among several compositors. If, as is frequently the case, different topics are included, or one side of the paper is devoted to business and the other to matters intended for the editors, any one may readily see how annoying it is not to be able to separate one part from the other, and how much delay may be occasioned thereby.

Newspaper Fileholders.

Dewey's new elastic fileholders (black walnut), size of the PRESS, *Harper's Weekly* and *Scientific American*, for 50 cents. Larger sizes to suit any newspaper, 75 cents. By mail, postpaid, 10 cents extra. Cash with all orders. Patent allowed. Address, DEWEY & CO., Publishers, San Francisco.

CAMPO, SAN DIEGO CO., CAL., July 3d, 1874.

MESSRS. DEWEY & CO.—*Gentlemen:* To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventors of this coast stand in their own light when they do not put their business into your hands. I remain yours truly,

A. M. GASS.

THE EXPLORERS,' MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 88 engravings. By J. S. Phillips, M. E. Price—cloth, $10.50; in leather, $12; postage 50 cents. Sold at this office.

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,

(Of the San Francisco *Evening Post.*)

This volume is now ready. It is a large 12mo of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loop, at Tehachape Pass, on the S. P. R. R.; Yuma, Prescott, Phœnix, Florence, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains. Calabazas, in the valley of Santa Cruz; Corrunnacion Peak, the Ariave Valley and the ruins of Casa Grande.

Also, numerous other engravings of mines and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the Mc-Cracken mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for $2 each

HINTON'S NEW MAP OF ARIZONA,

Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, $2.50 each; in covers, $1.50 each. For sale by

Special Attention to Fitting Eyes.

OFFICE—NICHOLL BLOCK, NINTH STREET,

(BETWEEN BROADWAY AND WASHINGTON.)

OAKLAND, CAL.

GOOD LAND

—IN A—

FAVORABLE LOCATION,

GUARANTEEING

Sure Crops Every Year.

The Reading Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends some 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is very healthful and comparatively desirable. The near proximity of high mountain peaks give cool nights during the "heated terms" which occur in our California summers.

Soft well water—remarkably sweet, pure and healthy—is obtainable at a depth of from 15 to 35 feet.

Wood is plentiful and easy to get.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

EDWARD FRISBIE,

Anderson, Shasta Co., Cal.

SAN FRANCISCO.

THE BERKELEY GYMNASIUM,

(A Preparatory School to the University.)

A First-Class Boarding School,

Established in the interests of higher education, and in opposition to the cramming system of small colleges and military academies of the State. The next

Term Will Commence July Twenty-Fourth.

EXAMINATION OF CANDIDATES FOR ADMISSION,

July Twenty-Second and Twenty-Third.

By request, instructions have been provided during the summer months for students preparing for the August examinations at the University. For catalogues or particulars, address

JOHN F. BURRIS,

Berkeley, Cal.

NOTE.—We desire to call special attention to the organization of our Grammar Department, separate from the Academical, and solicit the patronage of parents and guardians of small boys.

LAND! BOUNTY!! PENSIONS!!!

PATENTS!

Do you want to buy, sell or exchange lands or other property in any part of the U. S. or Canadas? Are you a Soldier or Sailor, in want of a Patent? Why not obtain more Bounty or Pension? Do you want to locate Government or State Lands without settlement? Why not? When I have the well-known Approved Soldiers Additional Homesteads, under seal of the General Land Office, and that can be located without settlement, upon any Government $1.25 or $2.50 lands, subject to homestead. The Sioux Half-Breed Scrip, for location upon unsurveyed lands.

Land Warrants and Scrip of all Kinds

For cash, or part on time. Good title given or no pay. Have you any lands with an imperfect title to sell, or choice vacant lands you know of which could be located to advantage; or claims not lawfully held, which we could contest. Let me hear from you in full, and I will do my best to inform you what is to your advantage.

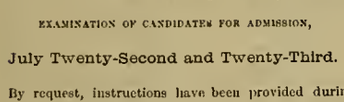
I will mail you a circular explaining all, and a copy of the new Pension Law. Address, (plainly)

D. H. TALBOT,

General Land, Scrip and Warrant Broker, SIOUX CITY, IA.

American Machine

AND



Model Works.

Experimental and Fine Special Machinery, Planing and Gear Cutting, Printing Press, Band Instrument and General Machine Repairing; Dies, Taps, Punches, Reamers and other Tools made to order. Models and Patterns for Inventors promptly executed in Wood or Metals. 514 Commercial Street, between Sansome and Leidesdorff, Third Floor), San Francisco, Cal.

I. A. HEALD, Proprietor.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco.

THE O'HARRA

CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:

One man, per day	$ 3 50
One man, per day	3 00
Wood, 1¾ cords at $3	7 00
Cost of 20 tons	$13 50
Cost of one ton	67½

From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address:

JUDGE WM. WEBSTER, Paymaster Mine, Reno, Nev.
LEWIS CHALMERS, Manager Exchequer and IXL Mines, Silver Mountain, Cal.
J. S. CONE, Vice-President Tehama County Bank, Red Bluff, Cal.
R. H. CAMPBELL, Superintendent Alterthought Mine, Redding, Shasta County, Cal.

For further information, apply to

D. J. O'HARRA, Reno, Nevada.

Established 1844.

JOSEPH C. TODD,

ENGINEER

—AND—

MACHINIST.

Flax, Hemp, Jute, Rope, Oakum and Bagging Machinery, Steam Engines, Boilers, etc. I also manufacture **Baxter's New Portable Engine** of 1877, of one horse-power, complete for $125; can be seen in operation at my store. Two horse-power, $225; two and a half horse-power, $250; three horse-power, $275. Send for descriptive circular and price.

Address J. C. TODD,

10 Barclay Street, N. Y., or Paterson, N. J.

Mill and Mining Machinery OF ALL KINDS FOR SALE by BERRY & PLACE

At the Old Stand, Market, head of Front Street, S. F.

FIRE! FIRE!! FIRE!!!

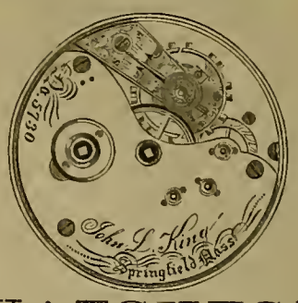
MINING INTEREST FOR SALE.

For a small amount, in several claims on one of the

RICHEST LEDGES IN ARIZONA.

Money needed for development. The ore will pay a handsome margin to ship to the city. Apply at this office.

AMERICAN



WATCHES!!

BUY THE BEST.

The New York Watches,

Made in Springfield, Mass.

Full Plate Movements Have the Following Advantages:

The winding parts of the Watch are superior to any in use in a full plate movement, for the following reasons:

They are attached to the barrel bridge on the top plate, so that in case of repairs any piece of winding part can be taken without removing the movement from the case or taking off the dial.

There is also an improvement in the manner of letting down the main spring, which is done by means of a pin attached to the click.

The winding parts are so arranged that there is hardly a possibility of either the ratchet, click, or click-spring breaking. There is a turning made in which to place the click, so that when the strain comes on it, the back rests against the solid plate, thus making it impossible for it to break.

In case the main spring breaks, the barrel can be taken out without disturbing any other part of the Watch.

The train of the Watch is run into the solid pillar plate and not into bridges screwed to the plate, as is usual; this avoids all danger of any alterations in the depthing taking place.

The hair spring stud is attached to the balance cock in such a manner that it can always be adjusted to its original position.

The escapement is the most improved form of a lever escapement now in use.

The manufacturers claim an advantage in our potence, as it is not liable to change its position and disarrange the escapement, as is often the case in full plate Watches; also on the bearing for the lower center wheel pivot, the plate being so constructed as to allow a long bearing.

The movement can be taken down and put up with less trouble than any other movement made in the United States, showing it to be the most perfect in simplicity and durability.

Sold at the lowest rates possible for perfect time-keepers, by

GEO. FINCK,

Importer and Manufacturer of

Watches, Jewelry and Silverware,

At the very Lowest Prices.

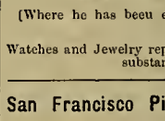
N. W. Corner of Kearny and Geary Streets, Opposite Market St., San Francisco.

(Where he has been established over nine years.)

Watches and Jewelry repaired in the best and most substantial manner.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,



Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Mining Share Market.

Business during the week at the several Boards has been moderately active with the slightly varying rates common for some months past, no advance or decline of any moment having occurred. The aggregate volume of sales has been notably small, the heaviest offerings having been of bonanza shares towards the close of the week and mostly on Eastern account, holders there having become alarmed at the break in these stocks caused by the non-payment of dividends by Con. Virginia and the fear that California will soon follow suit. Bonanza shares have in fact ceased to dominate the market, which has come to be controlled more by the Gold Hill, Julia, Ophir, Mexican and other north end stocks. As regards the future of the market we can only remark, as we have often done before, that no great animation or marked improvement in prices can reasonably be looked for till new ore bodies have been actually developed on the Comstock or satisfactory evidence furnished that such developments will soon be made. The reports of experts, the letters of superintendents and the opinions of the press, however favorable, will no longer suffice. Dealers of every class have had enough of them. Only ore developments will any longer suffice to keep life in the market or even stay it from further demoralization. Even in doctrinal matters faith without works is vain, in mining it has proved to be a delusion and a snare.

The Sutro tunnel having made connection with the Comstock lode, the manager and the mining companies are in treaty with a view to a settlement of the questious so long at issue between them. That these questions will meet with early adjustment seems probable, as all parties appear to be animated with a spirit of concession, causing these negotiations to be conducted with less acrimony than aforetime. Seeing the benefits likely to be derived from the use of the great adit, it may be expected that the mining companies will be more liberal and Mr. Sutro less exacting than during the earlier history of the enterprise, when both its completion and its practical utility were matters of doubt.

At no time since its inception has the business of mining for the precious metals on this coast been in a more healthful or promising condition than at present, and it only requires that this industry be now pursued in a prudent and economical way, to establish it on a permanent, profitable and every way satisfactory basis.

Significance in Bells and Whistles.

We read in the *Railway World* that a number of locomotive bells of various shapes and composition have recently been cast at the Altoona shops, from which a selection will soon be made for the purpose of finally establishing a marked distinction between the sounds produced, respectively, by the bells of freight and passenger engines. A corresponding distinction will also probably be made in the sounds produced by locomotive whistles. The success of this undertaking will manifestly render good service by enahling railway employees and the general public to distinguish the character of an approaching train while it is still at a considerable distance, and valuable infercnces may often he drawn from this iuformation. The period is probably near at haud when a bell of long, clear and pleasing reverberation, or other marked characteristics, will apprise all whom it may concern that a passenger train is approaching or passing, while a heavier, duller and more business-like sound will give notice of the movement of a freight train. In the bells already cast, marked variations of sound have been produced by slight changes in the composition, shape or distribution of metal. One bell, containing five parts of copper to one of tin, is in the key of A, and another bell of the same composition, but with slight variations in the shape or distribution of metal, is in the key of B flat.

Address, EXCELSIOR MANUFACTURING CO., 47 La Salle street, Chicago, Ill. Incorporated Feb, 16th, 1877. Capital, $1,000,000. Exclusive Territory given.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sen through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where he principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishere.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommed the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the eame.

Excelsior Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Potosi District, Lincoln County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Sixteenth day of July, 1878, an assessment of Twenty five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at the office of the Company, 304 Post street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 20th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the Sixth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

FRANCIS P. DEVINE, Sec'y.

Office, 304 Post street, San Francisco, Cal.

Gover Mining and Milling Company —

Location of principal place of business, Room No. 8, 402 Front Street, San Francisco, California. Location of mine, Amador County, near Drytown, California.

Notice.—There are delinquent upon the following described stock on account of Assessment No. 36, levied on the 24th day of May, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Knox, Joseph A	567	100	$50 00
Knox, Joseph A	571	50	25 00
Knox, Joseph A	572	50	25 00
Knox, Joseph A	573	50	25 00
Knox, Joseph A	727	30	18 50
Stevens, Mrs H A	192	50	25 00

And in accordance with law and an order of the Board of Directors, made on the twenty-fourth (24th) day of May, 1878, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Gover Mining and Milling Company, Thursnay, the first day of August, 1878, at the hour of one o'clock P. M. of such day, to pay delinquent assessments thereon, together with costs of advertising and expenses of sale.

W. O. WILSON, Sec'y.

Office, Room No. 8, No. 402 Front Street, San Francisco, California.

Mariposa Land & Mining Company of California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the Tenth day of July, 1878, an assessment (No. 14,) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office No. 9 Nassau street, New York City, N. Y.

Any stock upon which this assessment shall remain unpaid on the Twelfth day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and the expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, 309 Montgomery street, San Francisco, Cal.

Orion Mining Company.—Location of Principal Place of business, San Francisco, California. Location of Works, Iowa Hill, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of July, 1878, an assessment, No. 2, of 70 cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 28 Sansome Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 9th day of August, 1878, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the 24th day of August, 1878, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors.

P. CONKLIN, Sec'y.

Office, No. 28 Sansome Street (up-stairs), San Francisco, Cal.

Seaton Mining Company.—Location of principal place of business, San Francisco, Cal. Location of works, Drytown Mining District, Amador County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-sixth day of June, 1878, an assessment, (No. 11,) of seventy-five (875) dollars per share was levied upon the capital stock of the corporation, payable immediately in U. S gold coin, to the Secretary, at the office of the Company, Room No. 58, Nevada Block, northwest corner Pine and Montgomery Streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of July, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the twenty-first day of August, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

JOEL F. LIGHTNER, Sec'y.

Office, Room No. 58, Nevada Block, northwest corner of Pine and Montgomery Streets, San Francisco, Cal.

Office South Comstock Gold and Silver Mining Company.—Notice.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of Trustees and the transaction of such other business as may be presented, will be held on Monday, the 19th day of August, 1878, at two o'clock P. M. of that day, at the office of the Company.

Transfer books will be closed on Saturday, August 12th, 1878, at the hour of 12 M. of that day.

J. M. BUFFINGTON, Secretary.

Office—Rooms 3 and 4, second floor, No. 309 California street, over Aetna Insurance office.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Seventeenth day of July, A. D., 1878, an assessment, (No. 4,) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of said Company.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, A. D., 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tenth day of September, A. D., 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. J. W. CLARK, Sec'y.

Office, No. 318 Pine Street, San Francisco, Cal.

Telegraph Copper and Silver Mining Company.—Principal place of business, City and County of San Francisco, California. Location of works, Gopher Mining District, Calaveras County, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of July, 1878, an assessment of three (3) cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at his office, Room 2, 528 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth (9th) day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

I. T. MILLIKEN, Sec'y.

Office, Room 2, 528 California street, San Francisco, Cal.

Office of Union Consolidated Silver Mining Company, San Francisco, June 15th, 1878.—The annual meeting of the stockholders of the Union Consolidated Silver Mining Co., for the election of Trustees for the ensuing year, and for the transaction of such other business as may properly come before it, will be held at their office, 309 California Street, Rooms 3 and 4, second floor, over Aetna Insurance office, San Francisco, California, on Monday, July 15th, 1878, at two o'clock P. M. Transfer books will be closed Friday, July 5th, 1878, at three o'clock P. M. J. M. BUFFINGTON, Sec'y.

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS,

CHEMICAL APPARATUS AND CHEMICALS, DRUGGISTS' GLASSWARE AND SUNDRIES, Etc.

512 & 518 Washington St., San Francisco

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Muffles, Dry Cups, etc., manufactured by the **Patent Plumbago Crucible Co., of London, England,** for which we have been made *Sole Agents for the Pacific Coast.* Circulars with prices will be sent upon application.

Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

☞Gur Gold and Silver Tables, showing tho value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

San Francisco Cordage Company.

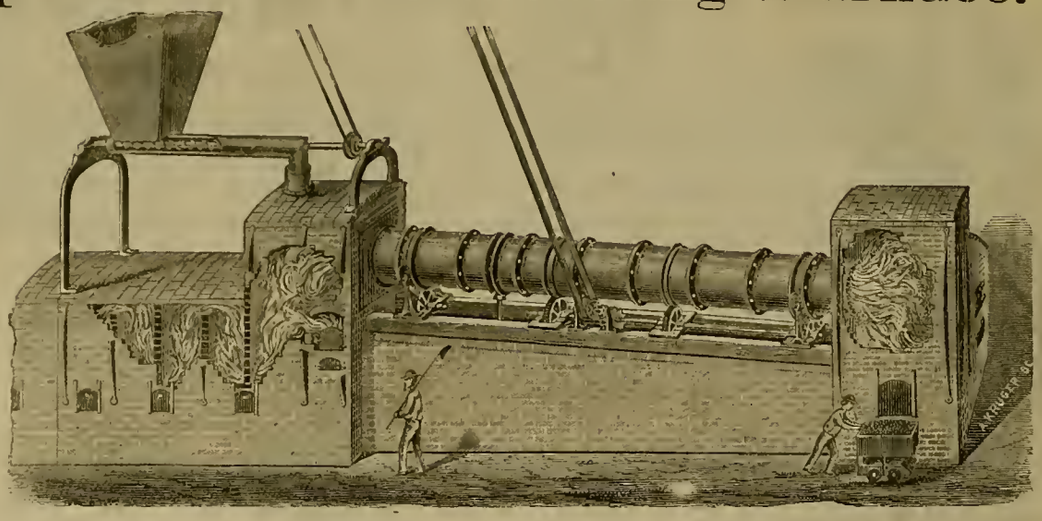
Established 1856.

We have just added a large amount of new machinery of the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes: Tarred Manila Rope; Hay Rope; Whale Line, etc., etc.

TUBBS & CO.,

611 and 613 Front Street, San Francisco.

Howell's Improved White Roasting Furnace.



This cut represents the most improved construction of this unrivaled Furnace, the superiority of which over all others as regards cost and capacity, as well as the economical and thorough oxidization and chloridization of ore, is now generally conceded.

In this Furnace, as covered by the Howell and White patents, are combined the three acknowledged requisites for the thorough and economical roasting and chloridization of ores.

First.—Continuous progression through and discharge of the ores from the furnace—while in the meantime they are, by being constantly showered through the heated air and gases within it, exposed in the greatest possible degrees to their reducing action.

Second.—Subjecting the ores to this showering process any length of time that may be necessary, according to the character of the ore, for its thorough reduction. In passing through the furnace it ordinarily falls about 1,000 feet, all the time in direct contact with the flame.

Third.—Increasing the heat on the ores as they are progressed through the furnace.

In this respect this furnace excels all others, as in none of them are combined all these essential requisites. It will chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade

The first cost as well as the cost of operating it is less than that of any other furnace of equal capacity.

It requires no especial skill in management that cannot be readily acquired by any one capable of conducting an ordinary silver mill.

We manufacture various sizes adapted to a five, ten or twenty-stamp mill, and will furnish plans by which any competent mill man can erect and operate it.

This furnace having the full or partial brick lined cylinder, embraces the devices covered by the patent to John Howell, as well as the original devices covered by the White patents. It has been erected and operated successfully at the following mines in California, Nevada, Arizona and Montana, viz: Camanche, Jefferson, Leopard, Utah, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry, Independence, Endowment and Alice.

At least ten of them are now in active and successful operation, in some cases reducing ores of the most refractory character.

These facts are a sufficient attestation of the merits of this furnace.

The undersigned, with Mr. John Howell, are the sole owners of the Howell patent, and they have perfected arrangements with him, and also with Mr. J. M. Thompson, who is owner of an interest in the White patents, and as such is possessed of as full and perfect rights and powers under the same as the patentee himself, by which they have acquired the exclusive right to manufacture these furnaces for the Pacific States and Territories. We hereby **caution** all parties against purchasing the same from any others but ourselves, or the said Howell or Thompson, as we shall prosecute all parties infringing upon the same. Knight's Water Wheel,

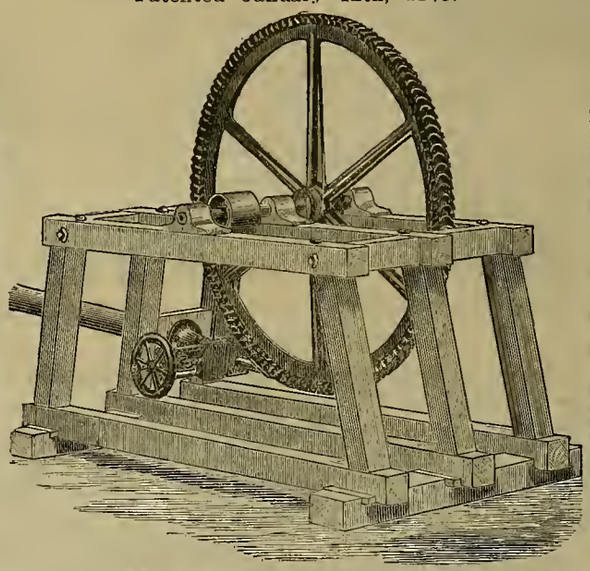
Patented January 12th, 1875.

This Wheel possesses more power for a given percentage of Water than any yet offered to the public. They are in practical use in many Mills and Hoisting Works, and never fail to give entire satisfaction, which facts speak fully for their efficiency, and render further comment unnecessary.



This Wheel possesses more power for a given percentage of Water than any yet offered to the public. They are in practical use in many Mills and Hoisting Works, and never fail to give entire satisfaction, which facts speak fully for their efficiency, and render further comment unnecessary.

The KNIGHT WHEEL is used in the following named Mills and Hoisting Works, to whom the Public are referred:

1-Eight-foot wheel, running Oneida Co.'s Mill, Amador county, Cal.; 60 stamps. Rob't Robinson, Supt.
1-Eight-foot wheel, running Con. Amador Mining Co.'s Mill, Amador county, Cal.; 40 stamps and two Hepburn pans. David Davis, Supt.
1-Eight-foot wheel, running Lincoln Gold Mining Co.'s Mill, Amador county, Cal.; 40 stamps.
1-Eight-foot wheel, running pump at same company's mine. S. D. R. Stewart, Supt.
1-Eight-foot wheel, running Keystone Con Mining Co.'s Mill, Amador county, Cal.; 40 stamps.
2-Four and one-half foot wheels, used in hoisting by reversible water power at same company's mine. O. C. Hewitt, Supt.
1-Four and one-half foot wheel, running Original Co.'s Mill, Amador county, Cal.; 40 stamps, one pan, one rock-breaker. J. R. Johns, Supt.
1-Four-foot wheel, running Gover Mining Co.'s new Mill, Amador county, Cal.; 20 stamps.
1-Eight-foot wheel, running same company's old Mill; ten stamps. John Palmer, Supt.
1-Six-foot wheel, running Talisman Mining Co's Mill, Amador county, Cal.; ten stamps.
1-Eight-foot wheel, hoisting and driving pump at same company's mine. John Treglown, Supt.
1-Four and one-half foot wheel, running Bunker Hill Mining Co.'s Mill, Amador county, Cal.; ten stamps. John Palmer, Supt.
1-Four and one-half foot wheel, running Gold Mountain Mining Co.'s Mill, Amador county, Cal.; ten stamps. J. C. Goodman, Supt.
1-Six-foot wheel, running St. Patrick's Mill, Newcastle, Placer county, Cal.; 15 stamps. Jno Townsend, Supt.
1-Eight-foot wheel, hoisting and running pump, compressor and hoisting at Sheba Silver Mining Co.'s Mine, State of Nevada.
1-Four and one-half foot wheel, running Luck Q. M. Co.'s Mill; ten stamps, Oregon.
1-Four and one-half foot wheel, running Republic Mill; 20 stamps, Nevada county, Cal. E. H. Dyer, Supt.
1-Six-foot wheel, at the Phunas Eureka, running 48 stamps, two pans, two rock-breakers. Wm. Johns, Supt.
2-Six-foot wheels, sent up to Sierra Buttes Mines, one to run 50 stamps and the other to run pans.
1-Six and 2 Four and one-half foot wheels, sent to Santsburg Mine, Sonora, Tuolumne Co. J. Leechman, Supt.

VOLUME XXXVII Number 4.

Quantitative Determination of "Slimes" in Water.

We notico in a late numher of the *Comtes rendus*, a simple and easily applicable method of determining tho amount of silt or mud, or what our mill men call "slimes" in water. It is frequently a matter of some interest to them to determine with ease and accuracy the amount of "slime" which is contained in the water flowing from their settlers. This is so easily and quickly determinod hy the simple apparatus, that we think a short description of it is worth the attention of mill men, and also of such others as are interested in hydraulic engineering.

The instrument is called a Pelometer, "slime measnrer;" it is composed of a two plane surfaces of glass strips about six inches long and about an inch wide. These strips are arranged in the form of a ridge, at an angle of about six degrees. The open sides are closed hy two parallel plates of hrass or tin. Along one of the sides of the glass plates is a graduation, which may be either in centimeters or in inches.

Previous to a nse of the instrument, it is necessary that onc arrange a numher of titrated tests for the purpose of comparison. These are contained in tuhes made of glass or of metal. They are ahout an inch long and one-third of an inch in internal diameter. They are closed by parallel glass plates which should he cut in circles, so as to enter the tuhes at either end, and press tightly against a cork which is perforated so as to enable one to see through the tuhe. There is an aperture on one side which allows the tuhes to be filled and emptied. Now when one fills the Pelometer with the water to he tested, and holds the instrument in a vertical position, he can, by direct comparison with the tuhes just mentioned, heginning with the thin layers at the bottom and going upwards, take as many readings of the thickness of the horizontal layers as he has comparison tubes at hand. A previously calculated tahle gives for these readings the contents of solid "slime" or silt contained in one liter, one gallon, or one cuhic foot, according to the unit used. In determining the coefficient of the instrument it is necessary to take the mean of many readings.

Instead of the comparison tuhes one may use a piece of white porcelain, or of white paper, upon which are drawn two black lines, 2 m.m. thick and 1 m.m. apart. (1 m.m. = ahout 1-25 inch). These ruled lines are to he moved up the glass sides of the instrumont, until on looking through it from the opposite a position is found where the horizontal layer of water and "slime" is thick enough to just hide the white space hetween the lines. From a special table, easily constructed, one finds the weight of "slime" contained in each liter, quart or other unit. In this method the light which makes the lines visihle has, of course, to make two passages through the layer of liquid before it reaches the end.

If the amount of "slime" contained in the water is too small for the Pelometer to be of use, one can then avail himself of a very simple arrangement, which consists of a cylinder at whose hottom is placed the ruled lines; the sides of the cylinder are graduated, and it is provided with a cock for letting out the water at the hottom. This is filled with the water to he examined and then hy means of the cock at the hottom the wator is allowed to slowly escape until the white space hetween the lines is just harely visible. This method reminds one of the old way of determining the transparency of the sea by lowering a white plate by means of a line until it was barely visihle.

It is necessary to remark ahout this method that of course it does not refer to silt, which is coarse enough to settle during the time of an observation, but to those impalpable powders of which so many tons arc discharged from our pan mills and which are such a source of annoyance and loss. It is also to be noticed that the source of light should he exactly the same and at the same distance in each case. For the most exact work tests should he made in a darkened room, with a candle at a fixed distance. Such details arc, however, nearly self-evident. The iustrument is so simple and easy of manufacture aud use that any intelligent person can make aud use it, and as there is, we believe, no patent on it there is no reason why the Pelometer should not be in use all over the State.

There is no doubt that the great production of "slimes" is the chief drawhack to our system of treating silver ores by the stamp battery and pan amalgamator. The amount of capital that lies useless, sometimes lost entirely in these beds, is something simply enormous, and at the same time there has heen steam power and wear and tear of machinery wasted in producing them. If this little instrument calls the attention of mill men to the amount of money which slips through their fingers day by day, it will he worth the trouhle it takes to make it.

The East River Bridge.

We illustrate herewith the East River bridge, counecting New York city with Brooklyn, as it will appear when completed. The labor on this bridge was commenced, on the Brooklyn side, on January 3d, 1870, upon the plans of the chief engineer, John A. Roehling, of Trenton, N. J. This gentleman, when he undertook this work, had already huilt two of the finest suspension bridges in the world—at Niagara Falls and at Cincinnati—and now he has added to his laurels another "wonderful monumeut of the engineering skill of the age." Soon after the completion of the plans Mr. Roebling died, and the work has been carried on by his son.

This bridge, crossing so great a water-thoroughfare as the East river and joining cities of such large traffic as New York and Brooklyn, required to he made high above the water so as not to interfere with navigation, and at the same time very strong, so as to bear the immense vertical strain which will inevitahly come upon it, as well as the great lateral strain arising from its hight and length of span. It will be seen from the following description how Mr. Roehling's plans are calculated to produce a hridge that will do the work assigned to it, and yet offer no impediment of any kind to river travel.

In the first place, there are no obstructions whatever in the river, the only two piers used in the bridge being allowed to stand not even in the water near the shore, but high and dry on the shores themselves. These piers are 280 feet bigh, reaching above the tallest spire of New York. The upper 150 feet of this pier is for the attachmeut of the cahles, the floor of the hridge heing only 130 feet high. There are two archcs in each pier, affording entrance to the hridge. Each archway is 32 feet wide, giving ample room for a railroad track, a carriage-way and a sidewalk. Each arch is 120 feet ahove the floor. Each pier contains 70,000 tons of granite. They were built by sinking huge iron-shod timber caissons, hollow and water-tight, to permit the laborers to excavate the foundations. On the Brooklyn side no suitahle rock for a fonudation was found at a reasonahle depth, and so the caisson remains with the pier upon it. The distance between the piers is 1,620 feet.

The bridge proper will weigh 3,600 tons, or adding the weight of the maximum number of foot passengers, railway trains, carriages, etc., 5,000 tons. It is supported partly hy four large cables, made of parallel steel wire into a bundle nearly one foot thick. The cahles are anchored in solid walls on the New York side, 1,337 feet from the pier, on the Brooklyn side, 837 feet. This gives the total span of the suspension bridge proper 3,794 feet. Beyond these anchoring points on either side the bridge is approached over arched masonry so high as not to interfere with the houses and streets. The cahles are so arranged as to afford resistance to horizoutal as well as vertical strain, thus preventing danger from gales. But not all of the vertical strain comes upon the cahles; it is shared with a numher of straight stays extending from the top of each pier toward the bottom of the hridge, so that, to quote from Mr. Roehling, "if the cables were removed, the stays would hold the hridge—only it would sag in the middle."

The hridge with its approaches extends far into New York city aud Brooklyn, having an easy grade on the outside of the piers, and affording a very safe and in every way convenient suhstitute for the old ferry hoats.

EAST RIVER BRIDGE, CONNECTING NEW YORK AND BROOKLYN.

THE MECHANICS' FAIR.—The Thirteenth Industrial Exhihition, under the auspices of the Mechanics' Institute, will open in this city on August 13th. This Fair is always the hest one on the Coast, and the manager this year promises many new features. As the exhihition each year has eclipsed former ones in attractions, the coming one will, without douht, he of greater interest than those preceding it. The space has nearly all been applied for already, so that the success of the exhibition is insured. Dewey & Co., proprietors of this journal, have been granted exclusive advertising and printing privileges, and will publish the ninth volume of the *Mechanics' Fair Daily*, a journal devoted to the interests of the Thirtecnth Industrial Exhibition. It will he of large size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute. Its columns will embrace a large variety of important industrial and scientific information, illustrations and well-written descriptions of the general features and most deserving and novel exhibits in the Fair.

THE gross earnings of the Central Pacific railroad for the six months ending June 30th compare with last year's earnings as follows: 1878, $7,839,537.03; 1877, $7,463,138.64. Increase, for 1878, $373,398.89.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS

Letter from Bodie.

EDITORS PRESS:—Possibly a revisit to Bodie, after three months' absence, including a trip over the new route via Sonora, may have afforded a few notes of an acceptable nature to the readers of the PRESS. Leaving San Francisco by the Stockton boat, July 3d, at 5 P. M., the passenger for Bodie connects with the train for Milton, at 8 A. M. next day; 28 miles miles east by rail, and the regular stage for Sonora, 36 miles farther, passing through Copperopolis, brings the passenger in connection with the new tri-weekly stage line to Bodie, 120 miles farther—in all 156 miles of stage travel, and a cut-off of about 175 miles in distance over the old Carson route. There is also a saving of $6 in fare. The new road over the Sierras is really an old one, built at great expense by Calaveras, Tuolumne and Mono counties, commencing at Sonora and ending at the Big Meadows; a fine, grassy valley on the East Walker river, and now possessing the county seat of Mono, at Bridgeport, 20 miles distant from here. For many miles this side of Sonora, the road is cut through a dense forest of pines, cedar, etc., the trees being very large, requiring great labor and expense in their extraction, roots and all, and removal. Where timber is thin, the granite cropping on the surface is great, and excavation necessary by means of powder, extensive and costly.

This road was finished ten years ago, yet through these years it has remained in a passable condition, indicative of the selection of route, with respect to freshets, water courses, snowslides, etc. The grades are uniformly even and comparatively easy of ascent. The scenery is continuously interesting, rising toward the main summit into grandeur only secondary to the Yosemite. From Hayes' station (a most romantic spot indeed), the distance to the summit is 12 miles, and the elevation attained is the difference between 6,100 and 9,800 feet, or 3,700 feet. The fall is a steady but not difficult one, and one is constantly interested in gazing above and below and in listening to the roaring torrents of the headwaters of the Stanislaus. There are several waterfalls and cascades of great hight and beauty. It may be something of a question as to the ability of the stage company to compete with the railroad route across the Sierras during the entire winter, but be that as it may, the enterprise is one of great importance to a large section of California and Nevada, both as regards passengers and freight. Already the stage owners express themselves as more than pleased with the prospects. In the matter of grain and fruit, the road must afford an extensive market to the people of Tuolumne, etc. It will serve to render a residence in Bodie and elsewhere over here much more pleasant, as the more avenues to and from, the more content the people will be with their isolated lot, and the development of mines must be reduced in cost perceptibly. In returning to San Francisco from Bodie, the connections by this route are an improvement on those in coming this way, as the stages can run to connect exactly with the overland train at Stockton. All in all, the Pioneer stage line, operating between Sonora and Bodie, may be set down as a fixture and one of the important institutions of California. In due time the mails and express will be carried that way as well as by Carson.

The revival of affairs in Bodie and Aurora is lending new life to the country all round about. The timber and hay interests pertaining to the mountains around all of the Big Meadows are great and growing; new roads are building and things in general are taking on the most substantial business airs. The town of Bodie has grown one-third since the snow melted, and the number of mills and hoisting works is in a fair way to be doubled ere the next snow-fall of consequence. The rich developments in several of the leading mines impart increasing confidence in the entire district, and it only remains for the Real Del Monte company, at Aurora, to strike it several hundred feet deep in proportion as Esmeralda produced on the surface, to inaugurate a line of mining activity here, of at least equal importance with the Wasboe in its best days. The indications could not be more favorable than at present, but we'll see what we'll see. During the past three months, Bodie and Aurora have been connected with the great world by telegraph and their newspaper facilities increased accordingly. This makes it more pleasant to be here. JOS. WASSON.

Bodie, July 12th, 1878.

NORTHERN PACIFIC CONNECTIONS.—Mr. C. B. Wright, President of the Northern Pacific Railroad Company, has authorized a survey for a railroad from the line of its road near Fargo, D. T., down the Red River of the North to the Canadian line, a distance of 150 miles, for the purpose of opening connections with the Canada Pacific railroad, which is now being constructed to the boundary line.

Alaska.

From an article on Alaska, prepared by Dr. Jackson, and published in the Chicago *Ledger*, we compile the following: As this is the latest of our territorial acquisitions, so it is the least known. Indeed, the interior regions of the country, away from the Yukon river, are as little known as Africa itself. The word Al-ak-shak means "the great land," and correctly describes the country. It is great territorially. From its eastern boundary to the island of Atton, the extreme western limit, is 2,200 miles in an air line. According to Prof. Guyott, this island is as far west of San Francisco as Maine is east. Consequently between the extreme east and west of the United States, San Francisco is the middle city.

The coast lines of Alaska, following up and down the bays and inlets, are about 25,000 miles, or once around the globe. Its total area is about as large as all the United States that lies east of the Mississippi river and north of the Carolinas and Alahama. Its great river, the Yukon, is over 2,000 miles long, and navigable for steamers from 1,500 to 1,800 miles. With a varying width from one to five miles along its course, it is 70 miles across the delta of its five mouths.

Alaska has the greatest mountain peak on the continent, Mount St. Elias, 19,500 feet high. It is the great island region of the United States, containing an aggregate area of over 31,000 square miles, equal to the size of some of our important states. It contains 64 volcanoes, ten of which send forth fire and melted rock. The seal fisheries make it a valnable possession; then the furs of the fox, martin, mink, beaver, otter and other animals make it worth having. Its fisheries alone are worth all it cost. The cod, salmon, halibut and herring being there in inexhaustible quantities. Its mineral resources will some day attract a large population and prove to the world that Alaska was no barren purchase.

The great surprise in connection with Alaska is the mild winter climate of the northern Pacific coast. The great Japan current of the Pacific that gives Oregon and California their delightful winter climate, first strikes the shores of our North American continent at the western end of the Aleutian islands and imparts its greater heat to the Alaska coast. Consequently, while in a higher northern latitude it yet has a warmer climate than New York city.

MINERAL PAINT DEPOSITS.—Mr. C. H. Sweetnam displayed in our sanctum this morning, a lump of black mineral deposit, much resembling asphaltum. It had been subjected, evidently, to the action of the ocean for many years and was so decomposed as to be readily crumbled or cut with a knife. Mr. Sweetnam informs us that this forms an excellent body paint when ground and properly mixed. If compounded with a little Prussian blue, it becomes a beautiful jet black, suitable for carriage painting, and equally as good as that which is sold for 55 cents a pound. Ledges of similar deposits, and representing all the fundamental colors except two, were first discovered on the beach near the old salt works. The brighter colors were first located by the discoverers to the neglect of the black, which was much the more valuable. When Mr. Sweetnam went to the spot he lost no time in placing his claim on the black ledge. He says there is enough of the mineral in sight to load a schooner, and he is confident that he has a paint bonanza in it. Mr. Guillroy, a well-known carriage painter of our city, has acquired a fourth interest in one of the ledges at an expense of several hundred dollars. He has prepared the material for experiment and is highly pleased with its results. We hope that the new lead may prove everything that is claimed for it, and that several rich men and another rich industry may be established in our community.—*Los Angeles Express.*

THE VERRAZANO DISCOVERIES.—The leading article in the August number of Barnes' Magazine of American history, is from the pen of Mr. B. F. de Costa, on the mooted question of the Verrazano discoveries. In previous essays the magazine has presented the writer's views upon the "Voyage of the Florentine," and the authenticity of the letter attributed to him; the present treats of his map, the North American section of which is reproduced now with the coast lines for the first time, as an illustration to the text. Able authorities have considered Verrazano the map-maker as a myth, but the light now thrown upon him dispels all doubt of his existence. A copy of the map is known to have been presented to Henry VIII. These interesting contributions to the history of early American discovery will close with a final article on the "Globe of Verrazano," one of the rarest treasures of the New York Historical Society.

A GYPSUM FIND.—A gypsum deposit has been discovered, says a Los Angeles paper, ten miles from here, and Mr. Bryd brought in a wagon load a day or two since, and it will be tested on some of our alkali lands. Dr. Wolfe has a mill for grinding the gypsum. Mr. Sesler, of this place, imported a quantity of gypsum from San Francisco, a short time since, for use on his lands, and we understand the experment has been highly satisfactory.

Lead Works Needed in Utah.

The low price at which lead is now selling has caused the mine owners and smelters of Utah to take into consideration such measures as seem best calculated to afford relief to this interest. As they cannot hope for any reduction of freights to Eastern markets, they have concluded, says the Salt Lake *Tribune*, to seek relief by building up such industries at home as would absorb this mineral. Fuel for smelting is now brought at great cost from Pennsylvania. There being, however, in San Pete valley plenty of coal that makes good coke, it only becomes necessary to build a railroad connecting these deposits with the lead mines to insure cheap supplies of fuel from that source. This done the production of lead would be greatly increased, causing further depreciation in the price of that article unless means were provided for utilizing it at home, to which end refining works would have to be erected, to be supplemented by others for the manufacture of sheet lead and shot, litharge, red and white lead, and lead pipes for supplying the domestic market. The manufacture of white lead alone would, it is contended, absorb a great portion of the base metal produced, which in turn would necessitate the manufacture of sulphuric acid and linseed oil, the former of which could be made very cheaply in Utah, because of the great abundance of sulphur near by. The Dutch system of making white lead could, it is thought, be inaugurated at a very trifling outlay of capital, but preceding it sheet lead works would be required, as rolling the metal out in thin sheets is an indispensable preparation. But the metal thus prepared has many uses, the product of the Utah mines being now made into sheets in England and supplied to China for tea packing and other purposes. The manufacture of shot, either by the tower or rotary table system, could and ought to be carried on there as it is in this city, and be made to pay. To accomplish all this would require a good deal of money, but the requisite capital ought to be easily commanded where such good and almost certain returns would seem to await investment.

The Great Mexican Railway.

The building of the great railway from Vera Cruz to the City of Mexico was a colossal feat in constructive engineering. The intervening country was superbly beautiful, and crossed at right angles by the great Sierra range, through which is one continued panorama of beauty.

The railway is 267½ miles long, has 18 lengthy tunnels, and many fine iron bridges. It cost 40,000,000 Mexican dollars, and is undoubtedly the finest constructed railway on the American continent.

The first 40 miles is straight, and on a gentle grade, rising slowly from the sea; then for a distance of 75 miles it crosses over three distinct ranges of mountains, each of which stands up like a colossal stair-case. This section is very crooked. Winding around the numerous canyons in the mountain, the train runs for many miles over the brink of precipices, almost perpendicular, 3,000 feet. The grades are 400 feet per mile; and the ordinary American locomotive finds the greatest difficulty in crossing unincumbered. But the company use an English engine—known as the Fairlie patent—which carries 10 loaded cars with ease. It is a double engine, or two engines connected, with their heads turned together, and 30-inch drivers.

At the west end of this division, which is at Boca del Monte, the road bed reaches its greatest elevation, which is 13,000 feet above the sea at Vera Cruz; from there it gradually declines through a continuation of broad valleys to the City of Mexico. These valleys are from three to 20 miles wide, entirely hemmed in by the tall mountains. Every foot is irrigated, and in a thorough state of cultivation.

ENGLISH ARTISANS AT PARIS.—We read that the movement set on foot by the Prince of Wales for sending artisan reporters to the Paris exhibition, is attracting considerable attention in the various manufacturing districts of the kingdom. Birmingham, Bristol and Edinburg have already reported to the committee sitting at the Society of Arts that active steps are being taken to promote this important work, and subscription lists have been opened to defray the expenses of sending over skilled workmen in various trades. It is understood that arrangements have been made, by which the artisans sent over will have secured to them both board and lodging on reasonable terms, and besides will have facilities given them for visiting industrial establishments in Paris. In return, it is made a condition that every artisan thus assisted must present a written report on his own special industry. These will be collected and printed for publication at a cheap rate.

COVERING THE MAN TRAPS.—The County Commissioners of Story county (Nev.), have ordered that all dangerous abandoned shafts be filled up or covered over. Since the opening of the mines of the Comstock many men have lost their lives by falling into old shafts. A number of men reported missing—men who walked off into the midnight, as it were—are thought to have found graves at the bottom of some of these old abandoned shafts. No less than three skeletons were found in one shaft a short distance below Gold Hill a few days ago.

Examinations for Phylloxera.

We lately made microscopic examinations of vine roots in a case of suspected phylloxera, and found the eggs and newly hatched larvæ of the insect in abundance. Though we regretted the discovery, it was no less a fact. It is time every man whose vines show signs of disease and enfeebled growth knew whether this ruinous pest was in his vineyard or not. Many have not the skill nor the appliances to make close microscopic examinations for themselves, but they should not be denied full knowledge. For obvious reasons a man who may have the scourge just appearing in his vineyard and proposes to fight it, does not care to have his ill fortune proclaimed through the newspapers. Therefore we make this proposition to subscribers of the RURAL PRESS: If any one of you find marks of disease in your vines, and desire to know whether the phylloxera is present or not, send samples of the leaves and pieces of the thick roots and fine roots or tendrils, addressed to the "editor of the RURAL PRESS, care Dewey & Co., No. 202 Sansome St., S. F." The root samples need not be large, and if roots and leaves be securely tied (not pasted) in strong paper they can be sent by mail at one cent per ounce postage. Put your initials on the package and at the same time send your name and postoffice address in the letter, enclosing stamp for reply. For all subscribers to the PRESS, who comply with these instructions we will make microscopic examination of the specimens sent, and communicate the results by private letter, free of charge. We will do this for all sending samples unless we should find the examinations were more numerous than we have leisure hours to spend upon them. The editor as a rule does not have time to attend to matters not intended for publication, but in this matter we are willing to "make time" in some way because of the importance of it. We are led to make this proposition to friends of the RURAL, because we believe that some of them are dwelling in darkness on the phylloxera question, through fear of the shade which the publication of finding phylloxera in their vines would cast upon their property. While this is going on the insect is multiplying. Therefore, we offer to tell our readers the facts, as the divorce lawyers say, "without publicity," hoping thus to win them to vigorous efforts to stamp out the growing evil. This offer of free work for individual interests must be restricted to those who are subscribers to the RURAL PRESS, and to such it stands open until notice is given of its withdrawal.—*Pacific Rural Press.*

The Hayden Geological Survey.

The United States Geological Survey of the Territories, in charge of Prof. F. V. Hayden, will leave Washington in a few days for the field of work in the West, Prof. Hayden and his executive officer, Capt. Stevenson, having matured their plans. The work during the present season will be an extension northward from the work of last year. The sources of the Snake and Green rivers, southwestern slopes of the northern end of the Wind River mountains; and the famous Yellowstone National park, which was brought into prominent notice by the surveys of Prof. Hayden in 1871 and 1872, are included within the area to be surveyed this year.

As indicated above, a part of the area marked out was explored several years ago by the survey. The work done was, however, more of a reconnoisance character, and the object this year is to make a final survey and to connect the work with the triangulation system carried north from the railroad.

The region is intensely interesting. In it are the sources of three of our greatest rivers—the Missouri, the Columbia, and the Great Colorado of the West. Geologically considered, there is no portion of the globe that presents more of interest to the scientist, artist or tourist. It is a region of former volcanic activity, as is abundantly evidenced by the numerous hot springs and geysers scattered through the park. Volcanic rocks are found everywhere and the collection of the varieties will be made a specialty by the survey. The geysers and springs will be carefully studied, with the view of developing all that may be learned concerning them.

Cheyenne, Wyoming Territory, will be the rendezvous of the party, and after spending a few days outfitting at that point, the various divisions will proceed westward via the Union Pacific railroad, from which they will strike northward to the respective fields of work.

The geological and topographical work will be carried on by two divisions, one of which will be in the Park and the other south and east of it. There will also be a party of primary triangulation, for controlling the geographical work. Special geological and paleontological work will be done in interesting localities. The economic resources of the areas will be carefully noted and specimens of the minerals and spring deposits collected. Chemical examinations of the spring waters will be made.

The topographical and geological work will be published in sheets, that will form part of the Atlas of the west, of which the Colorado Atlas just published is a type. As the work progresses, there will naturally be an advance, and the character of the work will become better and better, as the Atlas of Colorado is a great advance on all previous maps produced in this country.—*Alta.*

MECHANICAL PROGRESS.

The Art of the Eye-Maker.

The development of the mechanic arts as an adjunct or auxiliary of surgery has been rapid and great. In one line it may be illustrated by the success of the eye-maker. His methods are outlined in the *Polytechnic Review*. When a surgeon is forced to the last alternative of taking out an eye, it is desirable that he should leave as much of the ball as possible. Makers of artificial eyes call this the stump; and if it is large, it moves the artificial eye back and forth so naturally, that the change is not perceptible except to a close observer, who has previously known of the misfortune of the wearer. When the patient first goes to the maker of artificial eyes, the latter carefully studies the cavity, the size and shape of the stump, and the size of the eyelids, measured on their inner surface. These measurements differ greatly in different persons, and are very irregular in the same person, so that in no case can the porcelain be made symmetrically perfect. A sphere of porcelain is never used. The new eye is always hollow on the inner side. The extent of this concavity depends upon the size of the stump, which the porcelain must fit accurately, but without hugging. There are no rules of measurement for making a good fit, and for this reason a maker of artificial eyes should be an artist.

The material of the eye-maker is drawn for him at a glass manufacturer's into tubes about one inch and a half in circumference. He redraws a tube until it is a little smaller than a lead-pencil. Next he blows a bulb at one end, of the size of the eye-ball in his pattern, contriving to make it slightly oval to imitate the natural curvature of the eye. At the place where the iris and pupil are to be he flattens the little sphere, and in the center of the flat surface he applies a circular patch of black pigment. This is the pupil. Next follows a work of great nicety. With indelible colors taken from a palette, he imitates, on the flattened part of the sphere around the pupils, the iris, which he has previously studied in the sound eye. This having been done, a circular piece of clear crystal glass, flat on one side and convex on the other, is laid upon the pigments, with its flat side down. It is firmly fastened in place by fusing its edge with the porcelain with the aid of a blow-pipe. After this delicate operation, the front of the sphere should exactly resemble the sound eye, which it is to match with the exception of the small red veins in the eyeball. These are imitated by drawing out red glass to the necessary fineness, and applying bits of this glass thread, while yet hot, in vein-like shapes, to the cornea. They are fused into it under the flame of the blow-pipe. The work of imitating the natural eye is then complete. The fitting of the eye to its socket is an operation requiring much skill.

The Largest "Strong Box" in the World.

It is reported that the great vault which is now being built for silver coin at the United States Sub-Treasury in New York is the largest of its kind in the world; considered as a whole, even larger than that of the Bank of England. The *Iron Age* says it is 47x28 feet inside, and and 12 feet high, made burglar proof, designed for the expected large accumulation of silver coin under the operation of the new law. This new vault is building under a contract with George L. Damon, of Boston, who has about 20 men employed on the work. The estimated cost is $22,000. The outside granite walls are six feet thick, while the safe proper will be two inches in thickness on all sides, formed of alternate layers of iron and steel. The plates for the floor are laid directly on the stone flagging, supported by a solid bed of concrete, so that it would be folly for burglars to attempt to reach the treasure within by any process of excavation from outside. The top of the vault will be supported by rolled iron beams and girders let into granite columns, while lattice partitions of iron to support the bags of coin will divide the vault into a dozen stalls, arranged on either side of a longitudinal aisle. The general plan is not unlike that of an ordinary horse stable. Four openings in the ceiling and as many in the floor, covered by strong gratings, will provide for ventilation. The process of cutting out the brick floor of the Sub-Treasury building so as to convert two stories into one, is the laborious task now engaging attention, directly under what is known as "the gold room." When completed, communication between the gold room and vault will be by means of an elevator and stair-case, so that coin can be easily transferred.

COATING METALS WITH TIN.—The brilliancy and cleanliness of tin has long kept it in great favor for culinary and various other purposes, and an invention of Messrs Neuberg & Co., of Vienna, promises to make it still more readily applicable. They propose its electro-deposition by means of a zinc and carbon battery. The inner cell containing the carbon is half filled with chromic acid, and the outer cell containing the zinc is filled with dilute sulphuric acid. The articles to be coated with tin are put into a bath composed of protochloride of tin and cream of tartar, with or without chloride of tin. The proportions of these ingredients are: Eight parts of protochloride of tin, 16 parts of cream of tartar and two parts of the chloride if the latter is used. When it is present the tin coating is effected more rapidly, whereas when the bath is composed of protochloride of tin and cream of tartar only the tin coating is very white, but is not produced so rapidly as when the chloride is used. These ingredients should be dissolved in about 100 gallons of distilled water. The black plates are first "pickled" in any suitable manner, and then immersed in the above described bath or solution, and are allowed to remain in the same for a longer or shorter time, according to the thickness of the deposit or coating of tin required on the plates. While in this bath the plates or other pieces to be coated are connected by a wire with the positive end of the battery, while the negative end of the battery is connected with a piece of tin hung in the same bath. When the plates or other pieces or articles have been sufficiently coated with tin they are held over a fire in order to give the tin a lustrous appearance.

Building Spouts in Flour Mills.

Mr. Abernathy writes a letter to the *U. S. Miller* concerning the right and wrong in spouting for flour mills. Deprecating the guesswork which seems to rule most wheelwrights, he says: It is only important to know the lowest angle on which a given kind of material will slide freely and then if you have got the fall to give it greater pitch, do so, and it will be so much better; but if there is not the fall for the required pitch, make it. It does not matter how great a pitch the spout for any kind of meal may have, but for whole grain it is different. Wheat will run very freely at 22½ deg. on a smooth-bottomed spout, and so will any other hard grain. And I would not give a grain-spout a pitch of more than 35 deg. in any case.

Purified middlings will run very freely at an angle of 35 deg. on a perfectly smooth-bottomed spout, while any kind of middlings will run at 45 deg. Bran will also run at from 35 to 45 deg., according to its condition. For flour returns, dustings, etc., never fix a spout at less than 45 deg., and as much above it as possible. If comparatively flat spouts are unavoidable, be particularly careful to have them very smooth, and also have them broad in proportion. Small spouts are apt to choke under favorable circumstances, and sure to do so under unfavorable circumstances.

One thing should never be lost sight of in erecting a spout or series of them, and that is, to have the bottom level crosswise, else the material to be spouted will run to the lower side or corner, pile up and choke.

It does not matter how many different directions a continuous spout runs, each section should be level. This can be easily done if the spout be parallel by drawing a square line across the spout to level by. By a little attention to these suggestions, choking spouts may at all times, with ordinary care, be avoided.

CAR FOR ONE-RAIL TRACK.—There is building in Cleveland a car to run upon a one-rail track now in operation near the oil regions of Western Pennsylvania. The road is a single-rail track six miles long, and is said to be doing a large freight and passenger business. The car is not unlike an ordinary passenger car in looks. The *Iron Age* says: It is 28 feet long, eight feet two inches wide, with seats running lengthwise of the car as in English railway carriages. Underneath the car, and running its entire length, are two sections or boxes, flush with the outer sides of the car, three feet eight inches deep, with sufficient space between each section for the wheels and the rail they travel on. The sections serve to balance the car upon the rail, and also for the carriage of haggage. In the floor at each end of the car is a 34-inch double flange wheel, with the axles set in the floor with right angles to its length. The upper half of the wheel is, of course, covered. The rail is laid upon piles about four feet high. Along the piles, on each side, about a foot below the rail, are laid flat rails. The inner sides of the two sections that come below the rail have friction rollers that run snugly on the flat rails, thus further tending to balance the car and steady it while running. The car will cost about $4,000.

CUTTING RAILS.—It is a very difficult thing to cut red or nearly white hot rails so that they are of the same length when cold, as, if cut at different temperatures, they will vary in length on cooling. The following ingenious mode of obtaining a standard temperature has been adopted in some German and Russian rail mills: The glowing rails are looked at through a dark glass; when they have cooled to a certain temperature they can no longer be perceived. Using a dark blue or orange-yellow glass, *e. g.*, the rails may still be at a red glow, when the light radiated from them disappears in the dark glass. It may be considered that the light from two rails observed from the same dark glass disappears at the same temperature, and thus one is guided in cutting the rails while in this similar state, each rail after rolling being allowed to cool till it can no longer be seen at a given distance through the dark glass; thus they can be all cut of the same length.

SCIENTIFIC PROGRESS.

The Flow of Solids.

There has been a scientific congress in session at the Paris exposition. One of the subjects considered was the flow of solids, introduced by M. Fresca. An outline of his presentation of the subject is as follows: For all bodies two distinct periods are recognized—the period of perfect elasticity, which corresponds to variations of length proportional to the pressures applied; and the period of imperfect elasticity, during which the changes of dimension, on the contrary, increase more rapidly than the pressures. This second phase leads towards a condition in which a given force, sufficiently great, would continue to produce deformation, so to say, without limit, such as in drawing lead wire. This third period is designated by the author as the period of fluidity, and the greater part of his experiments on the flow of solids are related to it. This period of fluidity is more extended for plastic substances, while it is more restricted and may altogether disappear in the case of vitreous or brittle substances. But it is perfectly developed in the case of the clays and in that of the more malleable metals. Instances of deformations illustrating the period of fluidity were quoted in various operations of squirting, punching, forging, stamping, planing and turning, and principles were derived therefrom which lead the author to conclude that the idea of the flow of solids is, of all the modes of regarding their deformation, perhaps the one which most truly interprets all the phenomena of molecular mechanics, and of the internal constitution of bodies which underlie the various industrial operations. A curious instance of the collateral bearings of this theory is the fact that it is capable of explaining some geological phenomena.

The President said they must all be struck with the enormous development which this subject had taken in M. Tresca's hands. They appeared now to have arrived at something like mechanical analysis, corresponding to chemical analysis. He supposed that very soon the Government inspectors would be sufficiently learned to appreciate M. Tresca's system, and instead of adopting force would judge how weldings had taken place, and what was the quality of the metal, and, in fact, would have a complete laboratory where all such experiments could be tried.

Prof. Blake, lately of California, said the point which had struck him most was the geological aspect of the question which had long been considered on the other side of the Atlantic. At Newport, in Rhode Island, there was a conglomerate that had been cut away by the action of water, and it was found that the pebbles were washed out into the form of elongated ellipsoids, so regular and so geometrically uniform that they long ago suggested to some persons that they had been pulled out. That idea had been rejected at several meetings of the American Association for the Advancement of Science. But in the Rocky mountains he had encountered another conglomerate formed of homogeneous quartz pebbles, which had evidently been uniform in their constitution, but which had not only been elongated but in some instances compressed, so that one pebble was partly inside another. Others had been broken transversely and recemented. The conclusions at which he had arrived were that such pebbles had been elongated and flattened, and that the physiognomy of some of the mountains was due to the elongation which the rocks had undergone. There were vast regions in California where the rocks were sharp ellipsoidal points standing up through the soil, and every grain of sand and every pebble was an elongated and flattened ellipsoid. There had not only been elongation but compression. These conclusions were not commonly accepted, and had been a good deal ridiculed. It had been shown by Hungerford, in the United States, that fracture was not necessary to the flow of ice. If a block of ice were encased in a wooden mold, and kept at a temperature far below that of melting, it might be compressed and caused to flow through an aperture without any fracture. It was possible to reproduce the experiments, the results of which M. Tresca had shown, in one of the most vitreous materials with which they were familiar—solid water. They ought to consider all solids mobile under certain conditions.

NEW SACCHAROMETER.—A recent number of *La Nature* contains drawings and a description of Laurent's new saccharometer. The light from a fixed monochromatic yellow flame is passed through a diaphragm containing a plate of bi-chromate of potash, which absorbs the violet and blue rays. The yellow rays which pass it fall on a bi-refracting prism which turns on the longitudinal axis of the instrument, and in which the second image is diverged to one side and intercepted by diaphragms. One of these carries a thin plate of quartz parallel to the axis, which covers only one-half of the diaphragm. Its thickness is one-half wave for the yellow rays. Between this diaphragm and a second one the testing tube containing the sugar solution to be tested is placed. In front of the second diaphragm is the Nichol analyzer, an objective and a concave eye-piece. The latter three parts inclosed in a tube revolve, the angle through which they move being indicated on an alidade.

The Geology of Gibraltar.

In a paper read before the Royal Institution on this subject, as reported by *Iron*, Professor Ramsay, F. R. S., states that the main Gibraltar rock is a bedded limestone, which has been uplifted to high angles, being, in some cases, nearly vertical. The age of this limestone is not easy to determine, as there are but few fossils, and of these there is but one that can be recognized. It is a *Rhynchonella*, so closely resembling *R. cocinna* of the English oolites that the limestone has been assigned a Jurassic age. This limestone slopes away to the west, and forms the great eastern escarpment, and overlaying it are shales which form the lower slopes on which the town is built. Both the limestone and the overlaying shales are met with again on the African coast at Ape's Hill, Barbary, and there seems no reason for doubting the connection of the two portions at the time of deposition. From the fact that there are found recent Mediterranean shells at an elevation of 700 feet up the rock, it is inferred that the rock, after receiving its contour, sunk that much at least, and was after re-elevated. After the rock had been re-elevated, the sub-aerial forces modified the surface of the marine sands that covered the limestone platforms so that they came to form long sand slopes. It is probable that the land surface was greater then than now, and was re-united to Africa. The remains met with in the bone caves are a subject of great interest, and they show that the district was inhabited by mammalia common to Northern Africa. To solve the problem of the origin of the Mediterranean is not easy. It seems to have been a western extension of the inland drainage of Asia. There were probably two large inland salt lakes in the basin of what is now the Mediterranean, and these got rid of water by evaporation. An examination of the soundings of the sea shows how slight a change would be needed to bring about the present conditions. The sea is a very unusual one, and the Professor said it had, therefore, engaged his attention for years.

AN UNEXPECTED SCAVENGER.—An unexpected friend to man has been discovered in a kind of animalcule engendered by sewage, which prevents the decomposing matter from becoming a dangerous nuisance. Mr. Angell, the public analyist for Hampshire, having examined the sewage-polluted fluid in Southampton water, has discovered that where the suspended matters are thickest there is going on a silent destruction of the foul matters through the agency of millions of minute creatures, by some held to be of animal, but Mr. Angell believed to be of vegetable origin. On examining the muddy fluid through a microscope it was found to contain myriads of little brown organisms surrounded with a gelatinous substance. Each specimen was found to be active in its movements and of peculiar shape, being furnished with a belt of cilia round the center of the body, and with a long, transparent, and very flexible tail. After death these tiny atoms give off an odor similar to that of sea-weed, and change to a green color. During life they evolve bubbles of oxygen gas, which serve to purify the water from the effects of the decomposing matter on which they themselves feed. It is a pity, however, that man, by polluting rivers with sewage, should stand so much in need of this self-developed scaveuger.

DISTRIBUTION OF PLANTS.—Prof. Meehan remarks in the *Independent* that is one of the most remarkable facts in vegetable physiology that nature does not put species where they will do best, but evidently where she wants them, quite independently of their wishes and desires, if plants might be supposed to have any. Thus trees which nature places in swamps do much better when man places them on comparatively dry ground. And we know how remarkably well many plants thrive as weeds in our country, in comparison to what they do in their own lands. A recent illustration of this is a fact recorded of the watercress in New Zealand, where it has found a home as an immigrant from Europe. In that country and also in this, to which it has also been introduced, the stems under the most favorable circumstances seldom exceed one's finger in thickness; but in New Zealand the stems grow thicker than one's wrist and impede seriously the course of rivers and streams. The branches, here seldom more than a foot or so, reach a length of nearly 10 feet.

HONORS FOR PROF. HAYDEN.—We are glad to learn that the University of Rochester at its annual commencement on the 3d inst., conferred on Prof. F. V. Hayden the honorary degree of Doctor of Laws. In his letter communicating its action, the President, Rev. Dr. M. B. Anderson, says: "The Trustees and Faculty of the University desired to recognize by this action your great services to science through your personal attainment, as well as the almost unparalleled energy and success which have characterized your explorations, in regions hitherto unknown to the geologist as such. They did not hope to add in the slightest degree to your well-earned reputation, but they desired to express their appreciation of the honor you have done our country, and the State and city of your early residence, by those great labors which have linked your name with geological science for all coming time. The friendship of many years has made my official connection with this public act a source of the most sincere pleasure."

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

LEACHING.—*Chronicle*, July 20: This process is being used at the Advance mill and the prospects are that it will be a success. Ottokar Hoffman, of San Francisco, has arrived to assist Prof. Jones in treating the sulphurets. Mr. Hoffman is the introducer of the "leaching process" in this county, and modifier of it to the adaptation of ores on this coast. He will remain here two weeks, and is sanguine that his work will prove satisfactory.

THE FLINT.—Superintendent Ray has commenced work on the Flint, at Monitor. It is his intention to get out about 50 tons, to he worked by the concentration process at the Advance mill.

ADVANCE.—Milling ore continues to be taken from this mine and the mill is steadily at work, and within the next two weeks the result of its workings will be known.

AMADOR.

THE EMPIRE.—*Ledger*, July 20: The 80-stamp mill at this mine, formerly known as the Phœnix, is kept steadily running and on good ore.

OTHER MINES.—The old Seaton is still in abeyance. The Gover and Pennsylvania are running their full amount of stamps, and it is thought that shortly the two mines will lapse into one. The former is crushing excellent rock. Saturday evening the mine was obliged to suspend work on account of foul air. The Potosi labored under the same difficulty, though not to the extent of suspending operations. Crown Point is doing nothing. It is rumored that Hayward intends opening the old Hazard; if this is done, and the Seaton put in operation, Drytown will have, as in days of yore, a most favorable outlook. It appears to he the opinion of many old miners, with whom I have conversed, that the lack of success in some of our mines is due to the want of perseverance in not having the shaft sunk to a greater depth. One hundred feet deeper in many instances might put a different face upon the matter. The Montirichard mill continues doing well, running on eight dollar ore, hut a better grade is expected at greater depths. The Bismark mine, at Hunt's gulch, started up this week. Owen Kelly and another miner are taking out water. Capitalists below are understood to have the matter in hand. Negotiations are pending for the sale of the Moore mine to parties in San Francisco. Whether the sale is effected or not, work on the claim is to be shortly resumed. The search for a new ore-body in the Talisman is still prosecuted, with encouraging indications. The Centennial mining company have levied a second assessment of seven cents per share. W. S. Dunning is still taking out very rich rock from his mine.

BUTTE.

FORKS OF BUTTE MINING DISTRICT.—*Mercury*, July 19: The news from this district, situated in the canyon back of the Berdan place, on the Humholdt road, is encouraging. The Knowlton-Allen claim is being pushed rapidly towards a fine gravel deposit from which they expect good returns. One of the rules of this district is that no Chinaman shall he allowed to work or hold a claim in the district, and all the companies are pledged not to sell out to any of the Mongolian race.

CALAVERAS.

VEITH'S HYDRAULIC.—*Chronicle*, July 20: The gravel here looks splendidly where piping is now being done, and as there are hut comparatively few rocks to contend with it is being put through the flume at a tremendous rate, Unless we are greatly mistaken the next cleanup at the Veith mine will be the largest one ever made.

NORTH HILL MINE.—The company are now erecting large machinery. The flywheel weighs between 7,000 to 8,000 pounds. There will he about 100 tons of machinery erected on the mine altogether. The Superintendent of the mine is H. K. Drake. The machinery is capahle of running two tons a minute. Tbey will employ from 100 to 120 men, mostly Chinamen, with white men for Superintendents.

IN OPERATION.—Hoey & Sliter's new mill, in Old Woman's Gulch, has heen in constant operation duriug the week. Everythiug works well, the machinery runniug as smoothly as a clock.

THE BONANZA.—Work progresses without intermissiou at the Bonanza hydraulic, Tunnel Ridge, Moser & Co., proprietors. It is one of the steadiest paying claims in the district, and as the deposit of gravel is an immense one it can he regarded as a fixture in the way of mining. The impending water famine is putting all the miners in this vicinity upou their mettle, and at the Bonanza especially there is no lack of effort being made to render every inch to he ohtained available. The mine is runniug full-handed aud a large quantity of water is employed.

GOOD GRAVEL.—The gravel in the Duryea mine, Chile Gulch, has very much improved in quality, lately, and the claim is as largely remunerative now as at any previous period of its history.

MONO.

LOCAL MINING NEWS.—*Standard*, July 22: The work of developing in this and adjoining districts goes rapidly forward. Prospectors are confident that their "holes in the ground" will, hy more work, show up handsome hodies of ore, and are correspondingly sanguine of the future. The energy and perseverance which has characterized the movements of our mining men has not abated in the least, and those interested in the mines of Bodie district, who arrive almost daily, express themselves as more than pleased with the outlook. There are well authenticated rumors on the street that an important strike has heen made in one of our leading mines, hut the particulars will be withheld until its extent is fully known. The Miners' mill has been running on Red Cloud ore, for the past two weeks, and the returns are considered satisfactory. Shipments of ore will be continued for some time. Some high grade ore was also worked and yielded handsome returns. The Syndicate and Standard mills are both running on Standard ore, which is the hest evidence as to the amount of ore in this mine. The Dunderhurg mill is running smoothly, hut as there has heen no clean-up as yet it is impossible to tell just how the ore will turn out, though the superintendent asserts positively that it will he a grand success. Work in the Dunderburg mine is progressing finely and the developments are such as to warrant the running of the mill constantly. The hoisting works at the Spaulding are heing erected with all possible haste, and Bechtel mill is sufficiently advanced to state almost the exact day when it will start up, which will he about the 5th of August. Reports from surrounding districts are very flattering, and considerahle work is now heing done in Prescott, Laurel and Lake districts. The populatiou of this latter district is estimated at nearly 400, and a 20-stamp mill is on the way for that place from the railroad. Rock hrought in from other districts around us assays very well and taken altogether our prospects are hrighteniug rapidly.

NEVADA.

VARIOUS MINES.—*Transcript*, July 23: The anticipations of the lessees of the Deadwood mine are heing more than realized. There is at present about 35 tons of rock on the dump, and reliahle experts say that it will yield from $60 to $75 per ton, when crushed. The new air compressor at the Murchie mine will start up Monday. The Derhee mine continues to yield very rich gravel. Work progresses on the Montana, and they have a promising ledge in sight. A crushing was had from this mine a few weeks since, and the results were profitable.

ROUGH AND READY MINES.—The new hoisting works of the Irou Clad Co., located just helow Rough and Ready, will be ready to commense operations in about three weeks. Two crushings have already been taken from the mine, and the rock averaged $30 per ton. A fine looking 18-inch ledge is now in sight, and the prospects are encouraging. Messrs. Byrne & McCullough are runniug an extensive tunnel to tap the rich gravel lead in the old Gilham claim, near Rough and Ready. The indications for the early development of the mineral wealth known to exist there are promisiug.

FORDYCE DAM.—There is uow 56 feet of water iu the lake at the dam, extending back a distance of three and one-quarter miles. As soon as the supply of water from the lakes gives out for mining purposes, which will probably he in about a month, the inside of the dam is to be planked with inch lumher from the hottom to the top, a distance of 80 feet in hight. This is found necessary in consequence of the great leakage of water, which is caused hy the want of clay in the material in that section of country, and which is so essential in stopping the crevices hetween the rocks. The Fordyce is one of the largest and most expensive dams in the State, and is part of the South Yuba Canal property, which has recently passed into the hands of Alvinza Hayward.

PLACER.

THE SWIFTSURE CLAIM.—*Herald*, July 20: Gravel has been struck in this mine, located iu El Dorado canyon. Some two years ago the owners had a tunnel in the hedrock iu what is known as the Main Top ground, some 500 feet, and were at the time raising a shaft, confident in the helief that they might, any hour, hreak through into the gravel. No gravel, however, was struck. The tunnel was ruu further in, other shafts were raised, hut still no gravel. They, however, did not despair. Even afterwards, when they hecame convinced that they were heading in the wrong direction, and that the tunnel, which had cost them much money and years of hard work to run, would have to he ahandoned, they still were not discouraged. Putting their heads together and taking another view of the ground from the surface, they finally concluded to go around the point of the hill and start a tunnel in on ground helonging mainly to the same parties, known as the Swiftsure. They had proceeded with this tunnel somewhere hetween 400 and 500 feet, when a week or two ago, as we before said, they broke through the bedrock into the gravel, the channel of some old dead river, rich in hard, washed gold, thus realizing at last the reward of their persistency, and their day dreams of years. Such perseverance, such energy deserves to be crowned with success, and we again repeat we are heartily glad they have struck it. On striking the gravel they at once begun the erection of dump-hoxes, sluices, etc., for the purpose of washing, and as the yield from this out will no doubt be steady, we feel justified in adding the Swiftsure to the list of Placer county's rich drift mines.

SAN BERNARDINO.

RESTING SPRINGS.—*Semi-Tropic*, July 19: Two hundred and thirty hars of hase hullion from J. B. Oshorne, Resting Springs, were shipped hy Messrs. Lyon & Rosenthal, last Tuesday.

SISKIYOU.

SCOTT AND KLAMATH RIVER MINING.—Yreka *Journal*, July 20: Down at Hamhurg Bar near the junction of Scott and Klamath rivers, considerahle mining is heing carried on with great success this year, and several other companies are finding good prospects, indicating still greater prosperity in a short time. Morgan, Ramus & Taylor, at work on the Bar, took ont $1,000 last week, and will no douht continue to take out a rich yield every week. McCrary & Martin, in the river bank, find splendid prospects, and will soon he ahle to take out large quantities of the shining dust. The hydraulic companies are all husy, and as soon as they clean up, we may anticipate hearing of hig hauls of gold. The river claims, heing worked at a great expense, will soon be paying rich rewards for the immense labor and cost of tunneling under the Klamath. In about a month more Hamhurg Bar and Scott Bar will be about the liveliest and husiest mining camps iu the county, if not so now.

QUARTZ ON GREENHORN.—The Warren mill on Greenhorn was started up on Monday morning on quartz from the Cherry Creek ledge. It is the intention to crush 100 tons from this ledge to thoroughly test the quality of the quartz. They have resumed work on the Pennsylvania ledge, on the summit, and are taking out some excellent rock. Neshit a few weeks ago found the ledge in the old Sullivan claim agaiu, which had been lost some time, and has traced it down hoth the Greenhorn and Cherry creek side of the mountain for considerable distance. Another ledge ou which considerahle work has heen done has also heen traced down on both sides of the mountain.

SONOMA.

QUICKSILVER.—*Democrat*, July 20: The Great Eastern Quicksilver mine, four miles north of Guerneville, is running to its full capacity, turning out four flasks per day. Arrangements are heing made to put in a new furnace and to increase the numher of retorts so as to work up the supply of ore coming from the drifts. The Mount Jackson company have completed the new tunnel, and expect to start up the furnace in a short time. The region in the vicinity of these mines seems prolific in the production of minerals, as it is near them that persons are prospecting for chrome, coal and other minerals.

TRINITY.

BULLYCHOOPS.—*Journal*, July 20: Active operations have heen commenced hy the Bullychoop Quartz company. A trail will he graded, ditch dug aud arastra constructed, after which ore crushing will commence, when large results may he expected. Chas. Kuper, late of Junction City, is in charge of the work in the capacity of Superinteudent.

BIG PAY.—Some of the richest ground which has heen worked in this county for a long time has been run off hy J. W. Smiley at Douglas City this summer. He cleaned up the flume last week after a run of ahout ten weeks, and realized nearly $8,000, with the bedrock to hear from.

TUOLUMNE.

RICH QUARTZ.—*Independent*, July 20: Messrs. Jack Barry and Chris. Schulz are ahout to open a rich vein near the Odd Fellows' cemetery, Sonora. We have specimens of the ore hefore us, with free gold and sulphurets sticking out as thick as harnacles on the bottom of an old whaling craft. It is the intention to improve the property with appropriate works for reduction very soon. Fortune attends those who persevere.

MINING.—W. G. Long reports fine prospects iu the Live Oak mine. At a depth of 65 feet the vein averages ahout two feet and the ore shows well with free gold. He has several tons for crushing soon as the mill is ready for it. He also represents the Hunter as promisiug well, work heing constantly prosecuted.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—Gold Hill *News*, July 24: The 1300 station of the Consolidated shaft is being repaired and retimbered preparatory to continuing the repairs downward to the 1400 level. The heat is intense, heing greatly increased hy the extremely hot weather of the past four days. The main southwest drift on the 1300 level is being cleaned out and repaired, to assist the ventilation of a new ore discovery on the 1200 level. This ore is of a good quality and lies east of anything yet discovered in that portion of the mine. Just how much there is of it cannot yet he determined. A new drift has been started on the 1500 level from crosscut No. 1, intending to connect with crosscut No. 2 east of the ore vein. The daily yield of ore during the week has averaged 240 tons.

CALIFORNIA.—Daily yield of ore, 230 tons. The yield of ore from the stopes on the 1750 level continues good and is heing gradually increased as opening up the ore hreasts is advanced. During the first part of the week the yield was equal to 250 tons per day, the weather at that time heing much cooler thau at present, and the men in the mine being ahle to accomplish that much more. Sinkiug the C. & C. shaft is being pushed vigorously ahead. It is now down 76 feet below the 1950 level.

OPHIR.—The greatest point of interest in the mine during the week has heen the developments in the east crosscut (No. 2) from the northeast drift on the 2000 level. All access to that drift is closed, and while there is no douht hut that the drift has been in quartz and ore for the past two days, its extent and value is only a matter of conjecture, as no reliahle information in regard to it can he ohtained from any source whatever, and we do not care to puhlish any of the many rumors in regard to it, preferring to wait until the truth can be ascertained. The opening up of the 2100 station in the main incline is going steadily forward. After it is completed it will he necessary to sink the main incline enough deeper to form a sump hefore the 2100 drift can he pushed toward the ore vein.

JUSTICE.—Overhauling and repairing the pumping machinery and pumps is going vigorously forward. The water is gradually rising in the main incline. It will he hut a very short time now hefore the pumps are all ready to again start up.

SAVAGE.—A drift west has heeu started from the point of intersection with the Sutro tunnel on the 1640 level, which is intended to connect with the winze descending to the levels helow, so as to create a hetter ventilation of the lower levels of the mine. The temperature of the air of the Sutro tuunel is gradually lesseuing and as soon as a cool change of weather takes place will be quite comfortahle.

SILVER HILL.—The face of the north drift on the 900 level is showing some good quartz and ore in streaks as it advances. An east crosscut has heen started from the main south drift on the 800 level.

SUCCOR.—The ore vain in the face of the northwest drift on the 1050 level is showing hetter with each foot of advancement, the greater portion of the face heing in quartz of a fine mineral-hearing quality.

ALTA.—Sinking the main shaft is progressing steadily, though not at quite so rapid a rate of speed, on account of a much stronger flow of water coming in, which is probahly caused hy the stoppage of the pumps and the consequent rising of the water in the Justice shaft, the water hacking through into the Alta shaft.

CON. IMPERIAL.—The west crosscuts, Nos. 1 and 2, on the 2400 level, are heing steadily advanced through a fine quartz formation, carrying some very favorahle ore indications. The north drift in the Alpha grouud has nearly reached the Exchequer line, and will be continued hy that company directly through to their north line. Preparations are heing made for the speedy crosscutting of the vein at two or three different points in the Alpha ground.

BULLION.—Siuking the main incline helow the 1840 level is making excellent progress, the bottom in quartz and vein matter of a very favorable character.

CALEDONIA.—Sinking the joint winze helow the 1400 level is being pushed vigorously ahead, the bottom in good hlasting ground, and the flow of water gradually receding.

JULIA CON.—Some delays during the first part of the week were experienced hy the hreakages of the pump-rods and valves giving out, all of which has been overcome and everything is uow in good working order.

OVERMAN.—The east drift from the 1600 station of the main shaft is being steadily advanced, the face in porphyry. The west drift from the hottom of the winze on the same level running to meet it, is making good progress.

YELLOW JACKET.—On the 2400 level the south drift from the wiuze is in 76 feet; face in porphyry and quite dry.

UNION CON.—The joint east drift on the Mexican line ou the 1600 level is making steady progress, the face in hard hlasting porphyry. It is now in a distance of 470 feet.

CROWN POINT.—The north drift on the 2300 level is heing pushed vigorously ahead to open up the entire vein ready for crosscutting. Preparations are heing made for the extraction of ore again from the old upper levels.

SIERRA NEVADA.—The north drift on the 2000 level is making favorable progress, the face still in vein matter. Nothiug new of any other portion of the mine.

LEVIATHAN.—The indications continue to improve iu the north drift, occasional streaks of good quartz heing cut hy the drift, showing a nearer approach to the main ore vein.

BELCHER.—Sinking the winze helow the 1900 level is making fair progress. It is now down 312 feet on the incline helow the 1900 level. The south drift on the 2160 level is steadily advancing, the face in porphyry.

CROWN POINT RAVINE.—The new pump machinery is heing arranged for and will he placed in working position as soon as practicahle.

GOULD & CURRY.—The large air pipes are doing good work, and in a day or two more the drifts on the lower levels will he sufficiently cool to admit of a resumption of work at all points.

LADY WASHINGTON.—Crosscutting is ahout heing commenced on the south line on the 1300 level of the Justice mine.

BEST & BELCHER.—Work is progressing with steady vigor in the joint east drift on the 1900 level. Good headway is also heing made with the south drift on the same level. The faces of each drift are still in porphyry, and the heat is fearful.

HALE & NORCROSS.—The greater portion of the week has been spent in putting the pumps in good working order, two of the donkey pumps below the 2100 level having given out. Everything is again in good working order.

ELY DISTRICT.

RAYMOND AND ELY.—*Pioche Record*, July 23: The compressor is in place and ready to operate.

Every piece of machinery fitted to a nicety. The receiver is also in position and it only remains to make connection between the compressor and receiver, the pipes from the pump shaft with the receiver. Work in the mine continues as usual.

MEADOW VALLEY.—During past week running night shifts for cleaning out drifts, as it was found impossible to do it in the daytime, the engine being kept busy all day hoisting screenings. Mill running steady and doing good work.

RICH ORE.—The 35 tons ore taken from Tem Pahute to Reveille to be milled yielded from $204 to $760 per ton. This ore was taken from the Inca mine, owned by Mr. Russell, who was severely burned at Duckwater a few days ago.

LEACHING.—The ore tank built at Bullionville for the purpose of trying the leaching process on the tailings there having proved a success, four more tanks are about being erected and a large supply of chemicals necessary have been sent for. The dump of the Pioche mine, on Meadow Valley street, has been leased for the purpose of leaching the screenings, the party leasing paying at the rate of 50 cents per ton for the privilege. It is thought that it can be made to pay well.

HILLSIDE.—The furnace at Bristol which was shut down on Friday, the 5th, started up again on Tuesday morning and was running successfully at last accounts.

ORE FROM THE BACK LEDGE.—From the Mazeppa mine were shipped about 15 tons of ore to the Dry Valley mill last Saturday. No attention will be paid to the claim of the Alps Co. to this ore.

PIOCHE BULLION.—$8,798.81 in bullion was shipped during the week.

WARD.—Times here are very dull, not over a dozen or two of men at work in the neighborhood and the future prospects not cheering.

EUREKA DISTRICT.

MINING ITEMS.—*Sentinel*, July 20: The K K furnace will not be in operation again until the mine is placed in good working shape. One of the furnaces at the Eureka Con. has been shut down for repairs. It will be ready to resume next Monday. The new machinery for the Phenix hoisting works is being put in place. The Eureka tunnel is in 325 feet, with favorable ground. A portion of the machinery for the Hoosac hoisting works has arrived. It is rumored that the Hogden mine at Secret canyon will soon resume work. There has been a strike of 20 inches of first-class ore at the Two G mine at Tybo. Up to the 10th inst. the Tyho Con. had shipped $22,000 on July account. The Geddes & Bertrand is looking better than ever in its history. Messrs. Arrington and Bartlett, it is thought, will realize a cool hundred thousand out of it. Wells, Fargo & Co. shipped for the Richmond company this morning 10 dore bars valued at $18,880.13.

ORE FOR UTAH.—Thos. J. Taylor, who is engaged in purchasing ores for a Salt Lake company, shipped last evening to Mill Creek 12 tons of ore, valued at $3,000.

CHLORIDING.—The number of men who are chloriding on the mountain is much larger than ever before. There is great demand at the present time for mines to lease, and those who engage in the business, in most instances, are making it pay well, as there is little trouble in making sales of all the ore that can be taken out. Here is a chance for a large number of our unemployed men.

ANOTHER DISTRICT REVIVED.—From Mr. F. Barras, who left Eureka some weeks since for a prospecting trip and returned yesterday, we learn that he has devoted the most of his time to Bald Mountain, a district lying about 45 miles northeast of Eureka. Bald Mountain district was discovered some years since, but abandoned by the discoverers, as they could not induce capitalists to embark with them, although they exhibited some very rich gold ore.

Arizona.

MINING ITEMS.—*Enterprise*, July 20: News from Signal is to the effect that the mills are pounding away, with the usual productive results. The McCrackin Company's foundry works to a charm, and turns out all material necessary for the two mills. The '76 mill at Picket Post commenced crushing ore last week. The Turk mine, Globe, assays 546.65 ounces per ton. The Keystone, at Mineral Park, is turning out rich rock. The Peck mine is shipping a large amount of bullion. The Julius mine, Globe, shipped last week 2,104 ounces, 950 fine. A rich strike is reported to have occurred in the Stonewall Jackson mine at a depth of 125 feet. Mr. Holmes, of Walnut Grove, has discovered a very rich bed of gravel on the Hassayampa, in his neighborhood. He says it is the richest placer in the territory. A note from Mr. Marsh, at the Senator mill, says the mill is running night and day, but that water is growing scarce. The Miami mill now in its present condition is pronounced to be one of the best and most perfect mills on the Pacific coast. It is certainly well arranged and convenient in all its parts. There are 10 stamps, four pans and two settlers, rock-breaker, roasting furnace, 50 horse-power engine and boiler and all necessary machinery. It has a capacity of 12 tons in 24 hours, and certainly Globe district ought to furnish that amount of ore to keep one mill running. Mr. R. Wells, who has just returned from a trip to Bradshaw, reports business good at the Tiger and its vicinity. This is one of the richest mineral districts in Arizona, and the Grey Eagle the best mine there. It is situated favorably for working, and the ore is easily reduced. Its owners are now negotiating for machinery.

Dakota.

BLACK HILLS DISTRICT.

HIDDEN TREASURE.—*Pioneer*, June 27: After a 26 days' run, four or five having been lost through stoppage of mill for repairs, the company cleaned up $16,000 from a crushing of 850 tons of ore. The next run will be 30 days, and it is confidently expected the yield will surpass any yet obtained from this mine and mill.

PECACHO MINE, DEADWOOD.—Thirty stamps are running on ore from this mine. The extent of the new gravel cement bed cannot yet be determined. It prospects very rich, $50 per ton and more, and has the appearance of being a large deposit. Superintendent Edwards has let the contract, which will more fully develop its dimension; one from the Blacktail side of the hill, and one 20 feet below the present working tunnel. Twenty men are now employed at the mine.

THE Old Abe company, with 60 stamps, crush 600 tons of rock per week, at an average value of $12 per ton, netting the company a handsome income.

Montana.

PIKE'S PEAK MINES.—*Helena Independent*, July 17: There are but 25 whites here now, there being only two claims worked by them. Pioneer City has a mining population of 300, about an equal number of whites and Chinamen. White men are running some 18 or 20 claims. The gold yield of the camp will be about as usual. There are but four idle men in the camp, though the place is well supplied with working men. In fact, all parts of Montana are well supplied with laboring men, and some places overcrowded with late arrivals from the East. There is plenty of room for all who desire to settle on land, make homes, raise stock or go into some producing business on their own account; but it is an easy matter to overcrowd the country with men who depend on day wages for a livelihood.

MISSOULA ITEMS.—J. D. Richards, the finder of the recently discovered silver ledges some 20 miles above Missoula, near Heligate river, came into town this week for the purpose of recording his leads. He has discovered five leads, all of which gave an encouraging showing of silver and copper on the surface.

PIONEER AND PIKE'S PEAK.—*New Northwest*, July 18: These camps, once very prosperous, depending solely on the placers, have dwindled as these became exhausted. The Squaw Gulch and Irvine are the only white companies now in the camp, and the number of men employed does not exceed 25. The old placers have been slowly passing into the hands of Chinamen, but the main pay streak has held out as far as followed, and doubtless will be found further up and new claims be opened.

PHILIPSBURG ITEMS.—The Hope mining company is shipping from $15,000 to $20,000 per month. Supt. Carson is putting up a large Vanner building, and will be ready to take up and work the tailings by September. The Northwest Co. is shipping from $20,000 to $25,000 per month. The Algonquin has been proved to a depth of 200 vertical feet, and is good. After sinking 100 or 200 feet further, works equal in capacity to the mine will go up.

Oregon.

GALICE CREEK.—*Sentinel*, July 17: The English mining company have stopped work for the season. Ankney & Co. have also suspended active operations, but are still engaged in cleaning up, and running a tunnel. Green & Co. have crushed nearly 30 tons of rock this winter and expect a big yield. They will commence cleaning up in a few days. Two-thirds of the Taylor claim on this creek was last week sold by Wm. Byhee to Mr. Hockett, of Oakland, Cal. Mr. Wimer has purchased a half interest in the mining property on Butcher gulch, owned by the Simmons Bros., and preparations are now being made for active operations this winter.

CHICKEN CREEK.—At these mines, in Baker county, there has been much prospecting done for the limited amount of water to be had. The bar claims that have been opened pay from $4 to $5 per day, with what water they have; the creek has not been opened as yet. Every one believes it to be rich; the whole country is taken up; there are some 20 men there, the most of them working on the Sisley creek ditch, which is being pushed along as fast as possible. There will not be any water here this season to amount to anything.

Utah.

MINING ITEMS.—*Salt Lake Tribune*, July 20: Work is now being resumed on the north extension of the Horn Silver mine. By its present showing it bids fair to become a rival of the Horn Silver. Work is being pushed ahead on the Katie claim, bought a few days ago by Tom Couch and others. The owners of the South extensions are also to resume work again. The new town of Loeber is improving. A new building impetus will also be given to the town of Grampion. A big mining enterprise is now going on in Rocky district. A big body of high grade copper ore has lately been struck, and a tunnel is being run to tap it at a distance of 400 feet. Beaver Lake district is looking up. The Case mine, owned by Godbe & Co., is improving very fast, and large quantities of ore containing considerable gold are being extracted. The extension of this is also to be worked. The Wasco mine, in Star, is to be vigorously worked, and if lead was only selling for $40 per ton in Salt Lake, we would have the liveliest camp on the Pacific Coast. The Frisco reduction works start their new roasting and chloridizing oven to-day. They are receiving ores right along from the Horn Silver mine, and expect to make a big run the balance of this month. Quite a little stampede is being made by some of the miners here to Goose Creek, 70 miles west of this place. Some very high grade ore from there has been sent to this place. The Godbe furnace will be ready to start up again in a few days.

BINGHAM.—This will yet become a gold producing camp, another rich gold strike having been made in the Steamboat mine to warrant this belief. But it is said the Stuart, also, is turning out about 20 tons daily of ore carrying gold, and that it is now being reduced at Egan & Bates' mill. Good for the Old Reliable. She will yet lead the van.

News in Brief.

SECRETARY THOMPSON is inspecting the Boston Navy Yard.

YELLOW fever has been very fatal at Vera Cruz and Yucatan.

GOLD discoveries are reported in Paraguay and Patagonia.

THREE THOUSAND catfish will soon be put into Clear lake.

GEO. M. KIELL & Co., of Loudon, have failed for $6,000,000.

THE run of salmon down the Columbia river continues very light.

WORK on the branch prison at Folsom will soon be commenced.

THE grain crops of Utah are the largest ever raised in that Territory.

GRASSHOPPERS are reported at the head of Deer Lodge valley, Montana.

THE *Inland Empire* says that the Chinese sell liquor to the Indians at the Dalles.

FIFTEEN car-loads of Mormon emigrants arrived in Salt Lake city last week.

THE Santa Barbara oil well is in splendid indications, and yielding some oil.

THE Russians advertise great quantities of war material in Roumania.

THERE are 1,100 whites and 500 Chinese at work in the Cassiar mines.

IRELAND beat England and Scotland at the 800, 900 and 1,000 yard ranges.

THE Catholic church at Santa Rita, Monterey county, has been burned; no insurance.

THE Fresno *Republican* estimates the grain crop of that county at 750,000 bushels.

SOME of the Italian journals violently oppose the acquisition of Cyprus by the English.

MYERS, the scout who was captured by the Indians at Camp Curry, was roasted alive.

THE Utah Bank of London, with a capital of $800,000, has been opened at Salt Lake City.

JAMES GORDON BENNETT'S steam yacht *Jeannette* left New York for San Francisco July 16th.

THE honey yield of San Fernando valley, Los Angeles county, this year, is estimated at 200 tons.

THE estate of the late Isaac Friedlander is valued at $440,000, of which $280,000 is cash in bank.

THE Ute and Apache Indians have all agreed to go on their reservations, and no further trouble is anticipated.

SILVER dollars in considerable quantities are being exchanged at the mint in this city at par with gold.

JOHN P. JONES, Senator from Nevada, was honored by a public reception on his return home to Gold Hill.

THE Pintes who left Paradise valley during the excitement three weeks ago are returning and going to work again.

TWO ledges of cinnabar and two of silver have been discovered in Placer county, about 25 miles from Sacramento.

FURTHER strikes have occurred among the workmen employed in silk and lace manufactures at St. Etiune, France.

AN Indian brawl occurred at Sitka in which four Indians were killed. The natives are favorably disposed towards the whites.

MANY farmers in Polk county, Oregon, are cutting their wheat for hay. Not more than a half crop will be harvested.

SANTA MONICA, Los Angeles county, which three years ago was grazing ground, now has a permanent population of 700.

DENNIS JORDAN'S bid of $161,500 for building the Branch State Prison at Folsom, has been accepted by the Commissioners.

THE National Liberals of Germany admit that they expect to suffer some loss in the approaching elections for members of the Reichstag, but think they will retain a majority in that body.

THE water in the Carson river is receding rapidly, and as the snow has nearly all melted from the mountains, it is feared the water mills will have to shut down before the 1st of September—earlier than was anticipated.

THE salmon run in the Columbia is considered nearly over. The catch has been fair this year but not particularly encouraging. The canneries as a rule have put up a slightly larger quantity this year than last, but the business as a whole has not been satisfactory.

FORTY-TWO vessels, aggregating nearly 50,000 tons, are now lying in this port under charter to carry wheat to the United Kingdom. Fourteen vessels are engaged for other purposes to different foreign ports, and forty-four vessels are on the disengaged list.

A PARTY at Coos Bay has killed, skinned and boiled 100 sea lions. Some of these weighed as much as 2,500 pounds each.

THE orange crop of Los Angeles county has increased from about 5,000,000 in 1877-2 to nearly 8,000,000 in 1876-7.

THE shipping of ties and posts from Cuffey's Cove, Mendocino county, is lively. Six cargoes have been shipped so far this season.

ACCOUNTS from Phœnix, Tucson, and Yuma, Arizona, represent the heat as excessive, the thermometer ranging from 112° to 116°.

THE weather is very hot in England and on the Continent. In some parts of the Exposition building the temperature is unbearable.

STOKES, the murderer of Fisk, is reported to be in Cornucopia district, Nevada, looking after some mining claims in which he is interested.

TEN THOUSAND nail makers in England have struck for an increase of 30% in their wages, and 10,000 more will join the strike this week.

THE native Californian who was hung by a mob last week at San Jacinto for the murder of Palmerston, turns out to have been an innocent man.

PANAMINT is now entirely deserted by white men, a fine mill and numerous buildings remaining as monuments to its former high mining hopes.

THE Territorial Pioneers will celebrate the anniversary of the admission of California into the Union at Pacific Hall on the 9th of September.

THE General Government has ordered a survey of San Pablo and Suisun bays, and the schooner *Yukon* is coming down from the north to perform the work.

A PLAN to take the Yoakum brothers from the jail at Bakersfield, Kern county, by a mob, for the purpose of lynching them, was frustrated by the Sheriff.

IN this city, on the 18th inst., the wife of G. W. Schenck gave birth to triplets, three boys, weighing in the aggregate 17¼ pounds, all of them living and likely to do well.

THE exact amount of awards to American claimants by the American and Mexican Commission is $4,025,622. The Mexican government has thus far paid in $570,000.

ACTIVE preparations are apparent for a favorable change in commercial affairs in England. Reports from various centers of the iron industry are decidedly more encouraging.

IT is stated that an immense majority of the Russian people, as well as the mercantile community, and the wealthy as well as the lower masses, are heartily glad of a return of peace.

A BOILER in Davis' planing mill, at Barnesville, Ohio, exploded recently, destroying the entire building and killing three persons outright. Three more were fatally, and several badly, injured.

A CHINAMAN recently made application to Judge Sloate, of the United States District Court, New York, to become a citizen. The Judge denied the application under the decision of Judge Sawyer, of the United States District Court of California, in the case of Ah Yonp.

THE American schooner *Parallel*, on her way from San Francisco to Portland, boarded a Japanese vessel on which was found no living person, but only a number of dead bodies of Orientals who seemed to have been dead for some time. As there was no food on board they are supposed to have died from starvation.

A RARE SPECIMEN OF FOSSIL IVORY.—In the cabinet of Messrs. Smith & Patterson, of Sutter creek, is to be seen a specimen of ivory, that so far has proved to be a paleontological puzzle. It was found in the town of Sutter creek by parties sinking a shaft for water, at the depth of about 30 feet from the surface, embedded in a strata of blue mud, which here rests on a bedrock of talcose schist. The specimen is about four inches in length, three-fourths of an inch in width at the socket-end or base, tapering gradually to a point at the other extremity. The shaft is prismatic or thickest in the center like a double-edged bowie knife and slightly curved, the edges serrated, the teeth about the depth of a joiner's tenon-saw. The inclination of the teeth on one edge is towards the point, on the others the reverse. The joint appears to be of the kind known as ginglymoid, the articulation of the diarthrodial kind, which only admits of motion in two directions like a hinge—as the knee-joint or elbow-joint. It is evidently a powerful natural weapon, offensive and defensive, or both belonging to some of the extinct fauna of this coast, which lived and had its day away back in the many, far-off periods of the pliocene or post-tertiary, geologic epochs more easily written than comprehended. Will some modern Agassiz or comparative anatomist or paleontologist tell us what it is?

CHROMATE OF IRON.—There is some demand for this ore in San Francisco, if that containing something like 50% of the oxide of chrome can be laid down here at a moderate figure. It is not, therefore, an article that will bear costly transportation. If parties owning deposits of this ore will advise us by letter of location, quality, etc., we may, by publishing the same, help their chances for turning it to profitable account, provided the character and location of deposits will warrant.

JOHN L. BOONE, of this city, has received news of the death of his maternal grandfather, Henry Hawkins, of Silverton, Oregon, who had reached the age of 103 years. The wife of the deceased is said to have been the first white woman that entered Louisville, Kentucky.

The Engineer.

Utilizing the Power of Niagara.

An item in last week's Press announced the formation of a company to transmit the power of Niagara Falls to Buffalo, and there employing it for manufacturing and other purposes. The enterprise is audacious, and the projected details will he read with iuterest.

The principal part of the machinery will he located near the water's edge, below the falls, in the vicinity of that delightful spot called the Bridal-veil. The remainder will be on the bank immediately above. The great air receptacles, three of which will be 70 feet long by six in diameter, will be located below the bank, near the water, while the receiving reservoirs will be on the bank. The cylinders will be constructed of boiler iron, in the most substantial mauner. The perpendicular fall from the feeding hasiu above to the air receptacles below is 214 feet. The engineer's figures show that 200,000 pounds of iron will he required, and it is estimated that power enough will be generated to raise about 350,000 gallons of water 150 feet every minute. These resul s have heen obtained hy careful scientific tests, so that there is little doubt that they are nearly correct.

Gentlemen prominently connected with this enterprise own Day's caual, which was constructed several years ago by Mr. Day for water-power purposes, at an expense of nearly $1,000,000. This canal will play an important part in connectiou with the new project. It is 33 feet wide by 11 deep, and leads from a point just above the rapids, a mile across, to the bank below. At its lower terminus is a large hasin, 70 feet wide and 800 feet long and 11 feet iu depth. From the hasin a flume 300 feet long is being dug to the edge of the precipice. At the mouth of the flume will be a massive iron gate with an eight-foot openiug. The water from the flume will pass into the reservoir, which will be connected witb the air receptacle below hy means of large pipes, siphon-shaped. Attached to the cylinders will he a requisite number of large automatic valves, to let the water run out of the cylinders after the compressed air has been allowed to escape. The practical workiug of the machinery will he briefly as follows: After the water in the reservoir on the top of the hank is high enough to reach the hend of the siphon it will escape down the pipe to the air cylinders below. The pressure thus ohtained very soon closes the automatic valves. There being no escape for the water which continues to pour into the cylinder (each has its own feeder), the air which it contaius is compressed by the volume of water from above until it has as much expansive power when released as steam. The capacity of the reservoir and of the cylinders is so arranged that the reservoir will he exhausted by the time the desired compression has been obtained below. While the reservoir is again filling with water, that in the cylinder is escapiug, so that when the bend in the siphon is reached, the contents of the cylinder are exhausted, and it is ready for another charge. Thus the operation is repeated at regular intervals in each cylinder, and there being several of them, a coutinuous charge of highly compressed air is obtained.

There seems to he no doubt that the air thus compressed can he conveyed hy pipes a reasonable distance, and made to do valuable service at nominal expense. In France it is conveyed 50 miles. The loss by friction in transmitting it from the falls to Buffalo is placed at 50 horse-power on every thousand, which is scarcely worthy of meution. The projectors of this great enterprise are confident that they will he able to do the pumping for the City waterworks at figures which will make the preseut cost of the departmeut appear enormous. They are also confident that they can make compressed air take the place of steam in manufacturing, thus doing away with the necessity for fire or fuel. They are aiming to do wonders, and, what is more, the chances seem to be strongly in favor of their success.

The Oil-Pipe Line.—An exchange says: The survey for the seahoard pipe line has finally heen completed. It commences in the oil regious of western Pennsylvania in the valley of the Allegheny river, at a point one and a half miles helow Monterey station, on the Allegheny Valley railroad, and takes nearly a straight course over the highlands of Indiana and Cambria counties; descends the face of the Allegheny mountains; crosses the mountains and valleys of middle Pennsylvania; the South mountain range; the red sandstone plain iu front of them and the hills of middle Maryland to Baltimore, a total distance of 228 miles, equal to 1,202,828 feet. It passes about 14 miles south of the county town of Indiana; one mile south of Carrolton, Cambria county; crosses the Pennsylvania railroad at Elizabeth furnace, below Altoona; and the Broad Top railroad at McConnellstown; passes through Orbisonia, Shade Gap, Roxhoro, Shippensburg and Gettyshurg; passes one mile south of Westminster, and one mile south of Reiterstowu; follows the ridge hetween Patapsco falls and Guyron's falls, and terminates on Curtis bay, two miles south of Canton, on an inlet of Chesapeake hay, at Baltimore.

Advice to Young Engineers.

Mr. Eckley B. Cox, President of the American Institute of Engineers, recently delivered an address before the Alumni Association of Lehigh University. He gave the following points of advice to young engineers: The first is the importance to you of a thorough knowledge of the principles of book-keeping. An engineer should be able to construct a machine, for example, at the least cost and with the least waste consistent with the complete attainment of the object in view within a proper time, and should so keep his accounts that when it is finished he can show all the details of the expenses incurred for each of the parts, and for the whole machine, and can give a reason for them. In other words, he should know how to build, what it will cost, and why it will cost. Such knowledge can only be acquired by a careful study of accounts, and hy keeping the cardinal rules of hook-keeping before him, and is absolutely necessary if he wishes to make reliahle estimates. It is not necessary for him to he a good hook-keeper in the sense of heiug a good, rapid, and neat penman, and quick at figures in the ordinary sense of the word, but he should understand the general principles and methods of hook-keeping. I should therefore recommend you, if possihle, to ohtain permission to work a month or two in the office of the estahlishment where you may be, to get up and keep as many accounts and tables of the cost of production, materials used, time lost, work done, etc., in your department as convenient. You will he perfectly astonished to find how much you will learn hy it, how habits of economy will grow upon you, how methods of saving lahor and expense, or of increasing productiou will suggest themselves to you when studying your weekly or monthly statistical tahles, and how the losses by delays and hreak-downs in the works will become apparent to you. The business experience of our firm impresses upon me more and more the importance and value of such accounts. The more accurately and systematically they are kept, the more we find that the regularity of business aud our capacity of production increases, and the less the cost per ton of our coal hecomes. I do not helieve in good engineering practice that is not founded on a thorough system of accounts. We have tried it and find it a good investment.

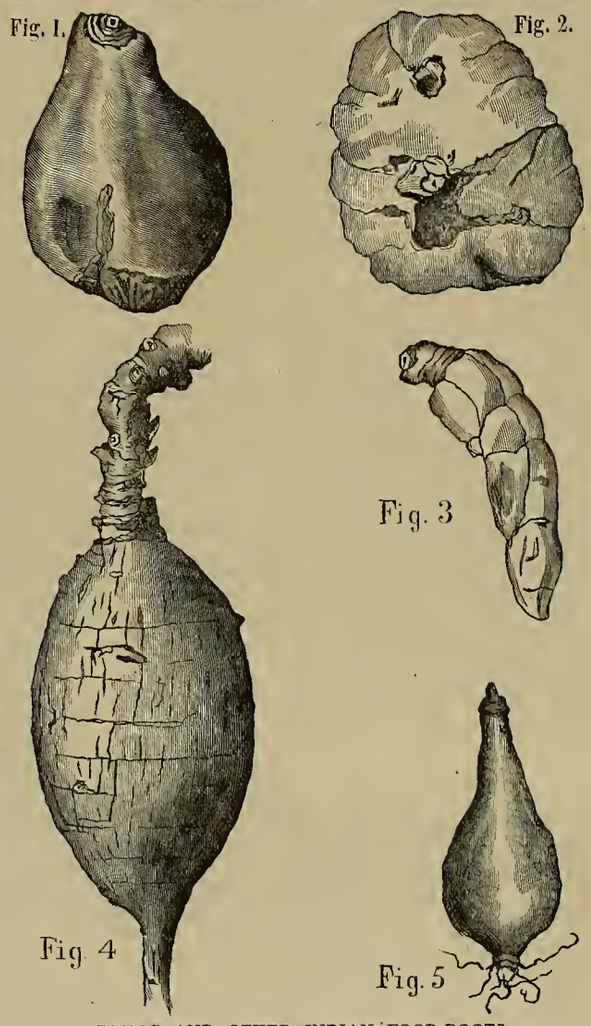
Be careful, when making a report or giving an opinion, to give your true views, uninfluenced hy any contingent fee (as it is euphouiously styled—hribe I should call it); the temptation is great I admit, aud the pill you are asked to swallow is often so carefully and thickly gilded that one is almost tempted to helieve it gold; hut if you ask yourself if I were retained hy the other side, or perhaps better, if I were retained by an impartial person, would my view be more or less favorahle? Never take a contingent fee, that is, do not make a report the price of which is to he in proportion to the favorableness of your opinion. Let the charge he the same, be the report good, bad or indifferent, and do not report on anything you are really not an expert in. It is not honest, and is had policy.

I have known engineers who, in their heyday, were perhaps envied hy younger memhers of the profession for their financial success, hut whose money was made by disgracing our profession and selling their honor, but their success has rarely heen a permanent one. I can remember when mining engineers were, for this reason, regarded by many persons who had heard of such proceedings with anything but respect. Try to live for your profession as well as by it; try to do something, however little it may be, to help it onward; move forward with the rest, and do not hold hack; for ours is eminently a profession of progress.

Above all, remember that au engineer should he proud of his profession, should always seek to elevate himself and it, and should never forget that a good engineer should be a geutleman.

Oregon Projects.—A Portland (Oregon) dispatch, dated May 30th, says: It is authoritatively announced that arrangements have been made between the Walla Walla and Columhia River Railroad Company and Messrs. J. C. Ainsworth, S. R. Thompson, S. G. Reed, W. S. Ladd, C. E. Tilton, and Dr. D. S. Baker, for the purpose of huilding a general system of narrow-gauge railroads to meet requirements of grain-producing counties hordering on the Upper Columhia and Snake rivers, and that the Walla Walla and Columhia River railroad will become part of the new enterprise, and that the work of extending the same will be commenced as soon as practicahle. It is also stated on the that in July or August next there will arrive in Portland 35 miles of steel rails, with a locomotive, rolling stock, etc., for the same enterprise.

St. Paul and Pacific Branches.—The St. Paul *Pioneer-Press* says: Work upon the branches of the St. Paul and Pacific railroad has been in progress for some weeks, and it is now certain that these important lines will be completed before the pleasant Minnesota autumn gives place to winter weather. Ahout 10,000 tons of iron was purchased in Pennsylvania some time ago, and as it is now arriving, tracklaying on the St. Vincent hranch will commence next week. The Alexandria line will also he hurried along, and as Manager Farley is superintending the work, its rapid progress can confidently be looked for. The troubles of the St. Paul and Pacific are over, and a completed system of road, stretching from St. Paul to the Red river and to the Winnipeg hasin, is only a question of half a dozen months.



CAMAS AND OTHER INDIAN FOOD-ROOTS.

Improving the Erie Canal.—There is growing conviction among New Yorkers that the preservation of the city's commercial importance is largely dependent upon the hest utilization of the Erie canal, and the Board of Trade are therefore congratulating themselves on the great increase of business since the opening of navigation this year and the reduction in transportation charges. The report of the canal auditor shows an advance of 80% in the uumber of tons carried during the first six weeks of this season over the same period last year, and 130% in the amount of tolls earned. The committee of the hoard, which has made a special study of the canal question, is very sanguine that through the ultimate opening of these water routes to free traffic and the introduction of steam power for towing, the vast commerce of the city may he easily maintained and extended. They unite in recommending the Belgian cahle system. which has been so long and successfully tried in Europe, as the most practicable means of applying steam, instead of horse-power, for towing, and are of opinion that the capacity of the canal with its present hoats would be almost fully doubled hy the change. This system has already beeu put in operation in this country, and it seems likely not to be long hefore it will entirely supersede the old and less efficient method.

A Plant Pretext for War.

It is commonly reported that the pretext which the Idaho Indians make for beginning the war which is now raging, was encroachment hy settlers upon "Big Camas Prairie," upon which grew large quantities of the "camas" hulbs, which the Indians esteem highly for food. The Iudian claim that the war was undertaken in this defense of their food resources is strongly denied hy the settlers, who assert that the "camas" was only a pretext, and that the war really sprang from the evil dispositions of the aborigines. However this may he, the "camas" becomes a subject of peculiar interest, as being ostensibly the hone of contention, and therefore we choose it and several kiudred hulhs and roots for illustration this week.

Camas root or "wild hyacinth" (*Camassia esculenta*) is shown in Fig. 1. This root resembles an onion in shape and a hickory nut in size. It hears a pretty blue flower. The root is dug in June and July. Wheu eaten raw the taste is pleasant aud mucilaginous; when hoiled it somewhat resembles that of the commou potato. The Indian mode of preparing it for future use is to dig a pit, line it with rocks, upon which a fire is made, and, when heated sufficiently, the heated stones are swept clean and the roots are heaped upon them; grass or twigs are next laid over the pile, and, finally, a covering of earth. After several days the pit is uncovered, when the white roots are found to be converted into a thoroughly cooked, dark-brown, homogeneous mass, of ahout the consistency of softened glue, and as sweet as molasses. Cooked in this manner, the roots are often made into large cakes, hy mashing and pressing them together, and, when slightly dried in the sun, they become rather pliahle and tough, and look like plugs of hlack navy tobacco. Its color does not recommend it to the taste, hut it is sweet, mucilaginous, and as agreeable as the fresh root, excepting a slight smoky flavor acquired in haking. In this pressed form it keeps softer than in the raw state or when simply cooked, and may he kept for a year or more. The roots, when boiled in water, yield a very good molasses, which is much prized, and is used on important festival occasions by various trihes. The Indians of Cape Flattery, the Nez Perces, of Idaho, and those of Pitt river, California, are the greatest consumers of this article of diet, under the name of camas root.

Kouse root (*Peucedanum ambiguum*) is shown in Figs. 2 and 3. The root of this plant is dug in April or May when in bloom. It grows on hills and mountains which are so poor that grass will not grow upon them. When fresh it is like the parsnip in taste, and as it dies hecomes hrittle and very white, with an agreeahle taste of mild celery. It is easily reduced to flour. When its hrown epidermis is removed, innumerable small dots are revealed. Both the roots and the flour will keep several months. It is sometimes called hread or hiscuit root hy travelers, and kouse root hy the Indians of Oregon and Idaho.

Prairie potato or "bread root," (*Psoralea esculenta*, Fig. 4.) It is also called Indian turnip, *pomme de prairie* of the French, and tip-sin-nah of the Sioux, who use this root very extensively. It is generally the size of a hen's egg, of a regular ovoid shape, with a thick, leathery envelope, easily separated from its smooth internal parts, which hecome friable when dry, and are readily pulverized, affording a light, starchy flour. It is of a sweetish turuip-like taste, is often cut in thin slices and dried for winter use, and is very palatahle, however prepared. The Indians of Kansas aud Nebraska consider this root an especial luxury. The Indians of the St. Croix river offer these roots as a peace offering to the Great Spirit.

Fig. 5 is wild sago (*Calochortus luteus*). The Utahs call it sago. The root is the size of a walnut, very palatahle and nutritious. The Indian children of California, Utah and Arizona prize it as the children of the whites do confectionery. The Mormons, during their first years in Utah, consumed this root extensively.

The Centennial Harvester.

Last year we gave the news about a combiued machine brought out in the San Joaquin valley, which claimed to take the grain from the stem and deliver it to you in sacks, thus doing its own heading, threshing and sacking as it moved over the ground. The inventor was Mr. Rice, of Modesto. Last year's work in the field, though encouraging, was not perfect, and the machine was remanded to its inventor and builders to remedy mistakes, and let the public see what they could do after another harvest's trial. A uumber of the machines were built during the winter by Messrs. Holt and Rice, of Stocktou, and spoken for by several leading San Joaquin farmers. We made arrangements some time siuce that one of our most cautious and trustworthy readers in the valley, Hon. C. J. Cressey, should watch the machine for us during the this season's harvest and advise us of its success or failure. Mr. Cressey ordered one of the machines that he might test its working to his own satisfaction, and he now favors us with assurance that it is a success.

The Centennial harvester is a combination of the ordinary header and separator. It is operated hy four men and 16 horses, and is moved at the rate of from two and one-half to three miles per hour. Its sickle bar is 16½ feet long, and at the speed mentioned cuts and threshes two acres of grain for each mile the machine travels. Its average cutting is from 35 to 40 acres per day. It cuts the grain the same as an ordinary header, and iustead of beiug put into a header wagon and hauled to a stack, it is, before touching the ground, carried on an apron to the separator, where it is threshed, run into sacks, which are sewed and dropped on the ground as the harvester moves round the field. Thus, with but one handling, the grain is headed, threshed, sacked and ready to haul out of the field to the warehouse or depot.

Mr. Cressey says he sets the harvester at work in his grain field in the morning, and at night he has from 35 to 40 acres cut, threshed and put into cars, aud at five o'clock the next morning the cars are at Oaklaud wharf, with the wheat ready to be placed on shipboard. Charmed with this quick work Mr. Cressey recalls the fact tbat from six to ten years ago (and before buildiug of the railroad), after spending weeks in cutting, stacking and threshing his grain, he had to haul it, with teams, 60 miles to Stockton for market, consumiug five and six days each trip, and at an expense at which the freight by rail diminisbes into insignificauce. Now he can cut his grain one day aud have it in market the next, and he can draw against it at once to pay his men and other expenses. This is quick work on a large scale, which we believe the world has never known before.

The cost of these machines is $2,000. This appears to he a large amount to pay for a single implement to use on a farm, but Mr. Cressey reminds us that every farmer who seeds 160 or more acres of ground, ueeds at least four horses for this work. Thus by using tbe power they already have, six farmers, adjoining each other, could unite iu purchasing a harvester. Four of the six could, witb their 16 horses, operate the machine, and the other two with a team, could haul the sacks of graiu from tbe field. Thus by helping each other they can cut, thresh, and haul from the field the wheat or barley from 35 to 40 acres each day, and thus turn their own resources to fullest account.

The account given us by Mr. Cressey is supplemented hy the results of a study made of the harvester iu the field by the editor of the *San Joaquin Valley Argus*. The editor says: "We visited one of the large harvest fields of Mr. C. H. Huffman; aud after following the harvester around for half an hour, we were fully satisfied that it was all that the builders and inventors claimed it to be; and also, that Mr. Huffman was master of the situation. The result of the test is, that with 16 good mules, four men, plenty of oil, and Mr. Huffmau as captain, pilot and engiueer, 40 acres of wheat can be cut, threshed, cleaned and sacked in one bour. Mr. Huffman pronounces it a perfect success, aud says that it does not lose one kernel more than the old header, and that $10 will pay for all the improvement necessary for its perfection. He is terribly in earnest, and so much pleased with the harvester that he bas already purchased two of them. We are assured that Mr. Huffman will save tbis year at least $9,000 in the harvesting of his crop, by reason of the use of the harvester instead of the common beader and tbresher."

Tbis testimony is unequivocally in favor of tbe macbine. Such being the case, we see no reason why tbe California inventors should not receive the $25,000 reward which tbe Australian government offers for such a machine.

It is fair to annouuce that the idea of cutting, thresbing and sacking grain at the same time, is also being worked out by another inventor who will have his apparatus in tbe field in time for test this year. The metbod is somewhat different from the combined machine described above, and it will doubtless soon be made public.

Tunnels.—Mr. Henry S. Drinker is preparing a work on tbe History of Tunnelliug, which is to include to this date, accounts of 1,624 tunnels, 282 of wbich are United States railroad tunnels, eight United States canal tunnels, while several, like tbe Sutro, are for mining and miscellaneous purposes, and about 1,300 are in foreign countries.

Useful Information.

Hight of Work for Filing.

Various ideas very naturally exist amongst mechanics, as to the hight at which the jaws of the vise should be set from the floor, for use in filing; arising, no doubt, from the varied nature of the work upon which the advocates of the different ideas have been accustomed to operate. In a "Treatise on Files," issued by the Nicholson File Company of Providence, Rhode Island, the following points are laid dowu:

For filing general work, the top of the vise jaws should be placed so as to be level with the elbow of the workman, which will be found to range from 40 to 44 inches from the floor—therefore 42 inches may be considered as an average hight, best suited for all hights of workmen, when tbe vise is to he permanently fixed.

If the work to be filed is small and delicate, requiring simply a movement of the arms, or right haud and arm aloue, the vise should be higher, not only in order that the workman may more closely scrutinize the work, but that he may be able to stand more erect.

If the work to be filed is heavy and massive, requiring great muscular effort, its surface should be below the elbow joint; as the operator stands further from his work, with his feet separated from 10 to 30 inches, and his kuees somewhat bent, thus lowering his stature; besides, in this class of work, it is desirable to throw the weight of the body upon the file, to make it penetrate, aud thus, with a comparative fixedness of the arms, depend largely upon the momentum of the body to shove the file.

It will therefore be seen, that in fixing the hight of the vise, the nature of the work and the stature of the operator should be considered, if it is deemed necessary to apply the the principle correctly.

Labor and Wages in Germany.—The Department of State has received from the United States Consul at Barmen a very full report on labor and wages in his district. For agricultural labor tbe pay varies greatly, according to the proximity to or remoteness from manufacturing centers, and ranges from 56 cents a day in the neighborhood of Bremen to 31 cents a day in the Lower Rhine valley, and as low as 18 cents in parts of Silesia. At Barmen, Crefeld aud Dusseldorf, carpenters, coppersmiths, plumbers, machiuists and wagonsmiths earn from 51 to 75 cents daily; saddlers and shoemakers from 47 to 52 cents daily; bakers and brewers, with board and lodging, from $1.42 to $2.14 weekly, and without board from 60 cents a day to $4.28 a week; farm hands are paid from $107 to $215 yearly, with maintenance; railway laborers from 56 to 83 cents per day, and as high as 95 cents daily for piece-work on tunnels; silk-weavers can earn from $2.15 to $2.85 a week per loom; factory women, $2.15, and children $1 a week. Business and wages are very low. In good times wages are 80% higher. The cost of the necessaries of life has increased 50% in 13 years, although it is now but little higher than five years ago. A man and wife, with two or three children, can live in two or three rooms in a poor and comfortless manner for $275 a year, and to support sucb an establishment all the members have to work 10 or 12 hours daily. For a family of six persons the cost is about $7 a week—an amount that few families can earn, as the depression of trade and the reduction of time allows few to do a full week's work, although wages are nomiually a trifle higher thau five years ago. The state of trade is deplorable. Factories are run and sales made at a loss, except, perhaps, the silk and button industries. Retail trade is somewhat more prosperous.

Care of Tools.—The following is taken from the posted rules of a Western manufactory: "Tools taken from the tool-room will be charged to the contractor or workman to whom they are delivered, who will be held responsible for their return, clean, promptly after using. These tools must not be passed from one to another; all transfers must be made at the tool-room. All lathe dogs, carriers, chucks, fixtures and general tools must be returned to their places on the tool rack, clean, after using; sockets belonging to the weigbt drills and hand latbes are not to be taken from their places for use in any other machine. In taking the socket from the drill or lathe, use a center key; never rap tbem out, as it springs tbem. Each machine must be tboroughly cleaned by the person using it after the job is done. No jobbing will be allowed in the shop except for tbe company. Throwing things in the shop, at any time is strictly forbidden. Those who disregard tbis rule will he discharged. All loud talking, wbistling, or gossiping with eacb otber must be avoided duriug working bours."

Weight of Track.—A conveuient rule for finding the number of tons of iron rails per mile of main track is: Multiply the number of pounds per yard by 11 and divide by 7. As a matter of couvenience we give the number of tous required for tbe various weights: 65 pounds per yard, 102 tons per mile; 60 pounds per yard, 94.28 tons per mile; 56 pounds per yard, 88 tons per mile; 45 pounds per yard, 70.62 tons per mile; 40 pounds per yard, 62.85 tons per mile; 35 pounds per yard, 55 tons per mile; 30 pounds per yard, 47.14 tons per mile; 25 pounds per yard, 39.28 tons per mile.

Preserving Fish.—Mr. John Eckart, of Munich, claims to have discovered a method for the preservation of fish in a fresh state by salicylic acid. His plan of procedure consists in impregnatiug fish by means of hydraulic pressure with a weak solutiou of salicylic acid, packing them in casks or cases, and ponring gelatine over them. The latter serves to prevent their becomiug stiff and dry. Prepared and packed in the above manner they may, it is said, remain from 10 to 15 days, and even longer, *en route* without detriment to their flavor or appearance; and Mr. Roosen, of Hamburg, who is turning this new system of preservation to practical account has received the most satisfactory reports respecting bis consignments of fresh and salt water fish to distaut countries. Trout caught near Munich, and treated according to Mr. Eckart's plan, arrived, it appears, at Bergen in Norway and in New York in a perfectly fresh state.

Growing Wheat Made into Bread in Less Than Five Minutes.—A certificate signed by a dozen citizens of Carrollton, Missouri, is to this effect: "We, the undersigned, certify that we were present at the Wild Moss Mills, James F. Lawton, proprietor, in Carroll county, Mo., on the 27th day of June, 1878, and witnessed the cutting, threshing and grinding of wheat growing in the field; and we hereby declare that agreeable to time kept by Mr. C. L. Bracken with a stop watch, and corroborated by several other watches, the wheat was cut with a 'Buckeye Dropper,' threshed, conveyed 40 rods to mill and ground into flour in three minutes and ten seconds; the flour cooked on a cook stove iuto griddle cakes in three minutes and 55 seconds, and into well-baked biscuits in four minutes and 37 seconds from the beginning of the time of cutting the grain."

The Hair Business.—Our human hair prospects are improving. According to the figures furnished us by the Bureau of Statistics our imports of human hair from France in 1874 were valued at $148,000; for 1875, $88,514; for 1876, $17,887; and for 1877, only $5,830. So it seems probable that in the course of a ycar or two more we can raise our own hair. These figures *hair* encouraging. Our Western Indians have also a good reputation for hair raising.

Good Health.

Tobacco's Devotee.

Ebenezer learned to smoke
When he was of a tender age,
And he could smoke and spit and chew,
And thought himself a sage;
And smoked till he was bald of head,
And chewed till he was almost dead.

He married Susan Glen, you know,
And she was pretty, young and fair;
But soon he smoked her till her face
Was just the color of her hair;
And kept her eyes and eyelids red
As those who weep for loved ones dead.

She loved him once, until she found
That his tobacco was his god;
He lived for it and worshipped it,
Till he was but a stupid clod;
And selfish self-indulgence seemed
The only hope of which he dreamed.

His poisoned children could not live,
Yet still he smoked and chewed the same,
And quarreled with his heartsick wife,
Because she knew he was to blame;
And all the burdens, toil and care,
Her slender shoulders had to bear.

The love he promised her went out
In smoke and chew, and chew and smoke;
And she would sadly mourn and grieve,
For it was certainly no joke
To see all manliness and use
Stewed out in strong tobacco juice.

Tobacco grew too weak in time—
Liquor was craved, and it was used;
The wife so sad and worn before,
Was now most cruelly abused;
And she would mourn and grieve and pray,
In hopeless sorrow night and day.

Paralysis, with lightning thrust,
Laid Ebenezer low at last,
And all his errors and his sins
Were with the unburied past;
And Susan, withered, sad and lone,
Had neither money, friends nor home.

Pitting in Small-Pox.—Mr. Gregory, of Merchants' College, Blackpool, England, believes that "pitting," the sad and permanent result of small-pox, ought rarely to be seen in auy civilized community. He starts with these facts, tbat poor people are pitted least, ricb people are pitted most, and no class of people are pitted under their dress. Poor people have less light in their homes, the ricb plenty of light, aud under the dress there is less light tban in eitber case. The explanation is a scientific one. The sunlight consists of tbree primary colors. The red, the blue and the yellow rays have distinct and characteristic properties. The yellow gives us light, and the red gives us beat, and the blue actinism. It is the actinic influeuce of the blue rays wbicb, in Mr. Gregory's tbeory, causes "pitting." No seed will germinate and young plants will soon perish if the chemically active rays—that is, the actinic rays—are filtered from the sunlight. A yellow blind drawn over a wiudow will absorb all the actinic rays. The pus of variolar pustules absorbs, by its yellow medium, the actinic rays, wbich results in corrosion of the tender flesh at tbe base, and tbus leaves tbe dreaded permanent "pitting."

Results of Sanitary Regulations.

The agitation of sanitary regulations has continued for some time, and it is fair to ask what has been the result of their enforcement. In a paper lately read before the Social Science Meeting at Cincinnati, Dr. Nathan Allen, of Massachusetts, said: It is not time yet to obtain the full benefits of such means; for while the advantages of observing some sanitary laws may be seen very soon, it will take many years to reap the complete beuefit of others. In certain localities in Great Britain, where these laws have been only partially applied for a few years, there has been witnessed a marked decrease in the amount of sickness and rate of mortality. From careful investigations it is estimated that this diminutiou will already range from one-fourtb to one-third; but it is the opinion of the best judges on the subject that, when sanitary scieuce is faithfully applied, there will be a decrease of more than one-third of the sickness and mortality which formerly occurred. The immense advautage, or value, which will be gained by this prevention of disease, in the saving of time and expense, in the preveution of pain and distress, in the geueral improvement of health and prolongatiou of life, caunot be estimated in figures or described in language. The more extensively and thoroughly these principles are applied, the greater good will they accomplish, and the more perfectly we shall find the laws of the external world adapted to the human system, showing that man has a far greater control of those laws than has generally been supposed.

Another important consideration is, that the more thoroughly sanitary agencies are applied, on a large scale, they not only serve directly to prevent disease, but furnish essential aids in curing it. Thus the more you improve ventilation and the quality of water, drainage and sewerage, and have regard to dietary habits and physical exercise, etc., the more successful will be the operation of all therapeutical agencies.

Healthfulness of Fruit.—Dr. B. F. Dunkley has made public some interesting facts derived from his own experience in regard to the healthfulness of fruit. When he first went to Dunksburg, Mo., 30 years ago, no orchards were there, and few vegetables were raised. The diet of the people consisted of corn bread, bacon and a little black coffee, without sugar or cream. Inflammatory disorders, especially such as relate to the lungs, brain, bowels and heart, prevailed in the winter, and were often attended with fatal results. Malignant dysentery, the pest of armies shut off from fruit, afflicted many of the inhabitants in the summer and fall, and in the spring it was not uncommon for whole families to be sick with scurvy, the disease so fatal to sailors on long voyages before canning fruit was discovered. Dr. Dunkley told his scurvy-stricken patients, to their great surprise, that their blood needed no medicine other than vegetable acids, and he ordered them to eat oranges, lemons aud sheep sorrels. Now fruit and garden vegetables are abundant in that locality, and the diseases are not of so malignant a type, and yield much more readily to treatment. When the orchards first began to bear, Dr. Dunkley noticed that those children whose fathers had planted apple tree eat plentifully of the fruit, both green and ripe, and eujoyed most excellent health, while children living where no apple trees grew, were dying of flux.

The Drainage of Cities.—A strong argument in favor of good drainage in cities has been furnished by the experience of St. Louis. The number of deaths in 1860 was nearly 6,000, and the average mortality for the succeeding four years was 5,600. The city then had a population of 150,000. In 1870 the deaths numbered 6,670, aud although there was a considerably increased mortality in 1872 and 1873, the average number of deaths for the last four years has been but 6,400, with a steady decrease. Yet the last census gave St. Louis a population of 310,000, and it is now estimated at not less than 450,000. As a fact, the mortality last year was less than the average during the period between 1860 and 1870. At the date first named, St. Louis had practically no sewers, and no rapid extension of the system was attempted until 1865. Since theu such improvements have been made in this direction that the city now has 180 miles of sewers. As no other great changes has been witnessed in a sanitary point of view, it is concluded that the decreased number of deatbs must be attributed to the development of the sewer system.

Cure for Sunstroke and Apoplexy.—A New York physician says: I believe sunstroke and apoplexy can be cured almost surely, if taken in any kiud of time.

1. Rub powerfully on the back, head and neck, making horizontal and downward movements. Tbis draws blood from the front brain, and vitalizes the involuntary nerves.

2. While rubbing, call for cold water immediately, which apply to the face and to the bair on the top and side of the bead.

3. Call for a bucketful of water as hot as can be borne, and pour it by dipperfuls on the back, head and neck for several minutes. The effect will be wonderful for vitalizing the medulla oblongata; it vitalizes the wbole body, and the patient will generally start up into full conscious life in a very short time.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Quantitative Determination of "Slimes" in Water; The East River Bridge, 49. The Week; Quicksilver Notes; Quartz Mining in Nevada County; Notices of Recent Patents, 56. Ostrich Farming in South Africa; Stock Operations vs. Mining, 57.
ILLUSTRATIONS.—East River Bridge, Connecting New York and Brooklyn, 49. Ostrich Farming in South Africa, 57.
CORRESPONDENCE.—Letter from Bodie, 50.
MECHANICAL PROGRESS.—The Art of the Eye-Maker; The Largest "Strong Box" in the World; Coating Metals with Tin; Building Spouts in Flour Mills; Car for One-rail Track; Cutting Rails, 51.
MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Dakota Ter., Idaho, Montana and Utah, 52-53.
MINING STOCK MARKET.—Sales at the San Francisco and California Stock Boards, Notices of Assessments, Meetings and Dividends, 60.
NEWS IN BRIEF on 53 and other pages.
SCIENTIFIC PROGRESS.—The Flow of Solids; New Saccharometer; The Geology of Gibraltar; An Unexpected Scavenger; Distribution of Plants; Honors for Prof. Hayden, 51.
THE ENGINEER.—Utilizing the Power of Niagara; The Oil-Pipe Line; Advice to Young Engineers; Oregon Projects; St. Paul and Pacific Branches; Improving the Erie Canal, 54.
USEFUL INFORMATION.—Hight of Work for Filing; Labor and Wages in Germany; Care of Tools; Weight of Track; Preserving Fish; Growing Wheat Made into Bread in Less than Five Minutes; The Hair Business, 55.
GOOD HEALTH.—Tobacco's Devotee (poetry); Pitting in Small-Pox; Results of Sanitary Regulations; Healthfulness of Fruit; The Drainage of Cities; Cure for Sunstroke and Apoplexy.
MISCELLANEOUS.—Alaska; Mineral Paint Deposits; The Verrazano Discoveries; Lead Works Needed in Utah; The Great Mexican Railway; English Artisans at Paris; Examinations for Phylloxera; The Hayden Geological Survey, 50. A Plant Pretext for War, 54. The Centennial Harvester, 55.

The Week.

The Trustees of the Mechanics' Institute have finally concluded to hold another fair, to open on the 13th of August. Already nearly all the room at command in their spacious Pavilion has been engaged, making the coming exhibition an assured success. The building is to be greatly improved before the opening of the fair, both in the matter of decorations, arrangements and general convenience. The Pavilion will be ready for the reception of goods early the coming week, and parties desiring to secure further space will have to apply for it at once.

About the middle of the week the announcement through the daily papers of the discovery of extensive deposits of gold-bearing sand on the beach near the Ocean House and within six or eight miles of the city, caused considerable excitement among the unemployed and that large class who are always on the lookout for something new and sensational, and many of whom hastily repaired to the new found gold fields, but with what results has not yet fully transpired. It has long been known that the beach sands in that neighborhood contained some fine particles of gold, but the best prospects heretofore obtained were insufficient to enthuse even the most chronic prospector or so much as pay Chinese wages. It is reported, however, that material of a better grade has now been found, some of it carrying as much as six or eight dollars per ton in fine gold, and that some of the parties at work are realizing fair wages, their washing appliances being by no means of the most approved kind.

Quicksilver Notes.

During the preceding week we passed through the towns of Guadalupe and New Almaden. At the former place we found several improvements being made. Some six months ago, the Superintendent, Mr. B. B. Thayer, finding that neither wrought nor cast-iron pipe would stand the action of the acid fumes passing through them, tried the experiment of using common iron-stone sewer pipe for the purpose of carrying the fumes from his condensers. Between condensers Nos. 1 and 2, he had constructed two series of pipes of this kind. The pipes were 20 inches internal diameter and the series were 50 feet in length, placed at an inclination of about 25°, slanting from condenser No. 1 to condenser No. 2. These pipes were connected with Portland cement, and were provided with numerous man-holes, which were closed in the same way. Whenever the flues became obstructed with soot, they were washed out with a hose, an operation which took only a few moments and which removed the obstructions as perfectly as possible from the smooth, glazed interior; so quickly this can be done that it does not interfere with the working of the furnace in the least, and the soot that is removed by the water is conveyed to settling tanks and allowed to separate and is treated at some future time. These common sewer-pipe tubes have been in operation over six months. Only a few of them show any signs of destruction by the acid fumes. This is, of course, due to the presence of iron in the clay of which they are made. But so well has Mr. Thayer been satisfied with their operation that he intends having a series of condensers made of the best fire-clay, in the following manner: The fumes, after passing from the furnace and into one ordinary brick condenser, are to pass into four sets of fire-clay pipes, 12 inches in internal diameter, and arranged so that the fumes pass alternately up one set of pipes, over curved connections, down the next, through another set of curved connections at the bottom, and up the next, and so on. The pipes will stand 15 feet high and be placed vertically and at distances of two and a half feet apart. They will be contained in a room, 50 feet long and wide enough for the series of pipes to be bent back on itself. The fumes will therefore be divided into four cylindrical streams, 12 inches in diameter and about 700 feet long. Each system, 12 inches in diameter and 700 feet long, will, therefore, expose 2,199.12 square feet of cooling surface, and as there are four such series, there will be 8,796.48 square feet. Very much better results are naturally expected from such an arrangement than from the old system of condensers. The flues are to be provided with man-holes at top and bottom, and it is the intention to shut off any one set of pipes by a damper when they need cleaning and flush them out with a hose, the water and soot being caught in troughs beneath each set of pipes and conveyed to settling tanks. In our opinion, the great difficulty will be to obtain good fire-clay pipes, which will resist the action of the acids. Mr. Steiger of San Jose, has undertaken this and intends to manufacture them from what appears to be a very fine variety of fire-clay, from Michigan Bar. We look to the results of this experiment with much interest, and remark that it is a curious return to the primitive system of "aludels," as used in Spain for centuries, with, however, the added improvements which a scientific technology has made possible.

Mr. Thayer has been carrying on some careful experiments as to the comparative economy of red wood versus Sydney (Wallsend) coal. They have at the hoisting works two equal boilers; the one is fired with wood, the other with coal. The amount of steam produced is kept the same in both and the fuels are carefully weighed. So far, at present prices, he finds the coal decidedly cheaper. This coal, as is well known, produces a great deal of soot, which caused great annoyance, as it filled the whole neighborhood, but a simple flue, of the width of one brick, built in the fire-bridge, not only produces an economy of fuel, but effectually prevents the escape of smoke from the chimney, a thin blue cloud being all that is visible.

It is rather a curious fact that at various times inflammable gas has escaped from fissures and crevices in the workings of the Guadalupe mine. It is reported that a substance resembling petroleum was found on one occasion. It seems that about the Fourth of July, one of the drifts, whose roof pitched upward, became partly filled with water, and remained so for several days. It was at length pumped out. The men knew that this gas had been accumulating there, and accordingly had compressed air blown into the place for 15 minutes. It seems, that instead of being in sufficient quantities to dilute the gas beyond the explosive point, they simply added air enough to make the mixture dangerous, and then entered with their naked lamps. An explosion ensued, of course. There were seven men seriously burned about the face and arms. But fortunately, nothing more serious resulted from it. It seems that a Davy lamp would not be out of place in such localities.

At New Almaden we saw one thing upon which the owners of the mine may congratulate themselves. Mr. J. B. Randol, the Superintendent, with his usual good sense, has been having a topographical survey made of the property under his charge, from the Hacienda, where are situated the furnaces, to beyond the new shaft, the Santa Isabel. The survey is being made by means of the plane table, by the well-known engineer, Ross Brown. It is very nearly finished, and presents already a very handsome appearance. The contours represent differences of level of 10 feet. When the survey is completed, it is the intention of Mr. Brown to make on tracing paper, on the same scale as the topographical, a map of all the workings of the mine, so that it may be laid upon the latter at any time, and the mine in all its parts can be easily seen at a glance in its exact relations to the surface of hills. This map has already been of great use in suggesting ideas as to the best ways of prospecting for new ore, and will, without doubt, be in the end of great service in this way, and the means of saving many times its cost. We are sorry to be compelled to say that this is the first mining property that we have heard of upon the coast, which has been so carefully mapped topographically by private interest. Such work is usually considered unnecessary, and we are glad to find that there are some, at least, of our mining men who can appreciate the help that a little science can be to legitimate mining.

The Santa Isabel shaft is being rapidly sunk to intersect the lower levels of the Randol shaft, which are being extended to meet it. We have some very fine photographs of the new machinery there, which is much heavier than that heretofore put up at the other shafts, in anticipation of more work being done there, as the ore bodies seem working in that direction.

At the Hacienda we found numerous changes in the way of condensing apparatus in the course of construction, which would take us beyond the limits of the present article were we to enter into a description of. We accordingly reserve its consideration for another occasion.

We acknowledge the receipt from the Superintendent of a very interesting translation of the German official report upon the mines and furnaces at Idria in Krain, and also an exceedingly valuable memoir by M. H. Kuss, M. E., upon the mines and works at Almaden in Spain. This latter is from the first number of the *Annales des Mines* for 1878. It has been partly translated by Mr. Fiedler, and it is our intention to give our readers the benefit of both these memoirs through the pages of the Press, and afterwards to put on record as much as possible, the state of the quicksilver interest in California, about which there seems to be so much misunderstanding in Europe and elsewhere.

Quartz Mining in Nevada County.

From what is being said by the Grass Valley and Nevada City papers we infer that greatly increased attention is being paid to vein mining in the vicinity of these places. That locality, as is well known, was the cradle of this industry and there it has been attended by as good average results as at any other point on the coast. For a time, and so long as only the tractable surface ore had to be dealt with, the business continued prosperous. Then for several years, and before either the metallurgy or mechanism of quartz mining had been much advanced, it remained in a very depressed condition, with hardly more than one or two claims on the list of remunerative properties. Some two and a half years since, and about the time of the advent of the Fryer furnace, new life was imparted to this interest, which has gone on increasing ever since. Whether the introduction of that method is to be looked upon as the cause or effect of this revival, certain it is the two were nearly coincident events, quartz mining having then received an impetus that will be likely to lead to its permanent prosperity.

In this connection it may be observed that the local press associates the name of Mr. Fryer with some of the live enterprises recently set on foot in that neighborhood, awarding this gentleman much credit for the energetic and intelligent manner in which he has engineered several of these projects to an assured success. Judging from the remarks of those journals we should infer that Mr. Fryer enjoys the confidence and respect of the community, into which his enterprise has carried him, in a high degree. The resuscitation of the old Murchie mine, the commencement of operations on Gold Flat and the rehabilitation of various other really good, but long neglected properties, are said to have been largely due to his persistent and well-directed efforts.

The Fryer Process.—Letters patent were received last week for improvements on the much abused Fryer process, by which it is claimed the process will be made a success after all. The company which took hold of the works at Grass Valley have been persistently but quietly experimenting and working for a long time, and the improvements suggested by experience have been patented. Affidavits filed for the benefit of the examiners at Washington go to show that very favorable results have been accomplished. Mr. Charles E. Sherman, Superintendent of the Fryer Nohle Metal and Mining Company, has been indefatigable in testing and experimenting with the machinery devised by Mr. Fryer, and in due time will probably show the public what can be done with the improvements recently patented. We shall be pleased to rejoice with the mining public whenever the company definitely establish the successful working of this process.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Fruit Cutting and Pitting Machine.—Chas. P. Bowen, Oakland, Cal. This device consists of an endless belt, with peculiar self-adjusting carriers, which are revolved by suitable mechanism. Connected with this is a tube with extended springs, carrying knives that cut the fruit into properly sized pieces, and permit the pit or core to pass out of the way through the hole, while the separated fruit is carried to a suitable receiver. In many localities much fruit is allowed to go to waste, and not preserved or dried, for the simple reason that it costs so much to pit and prepare it for drying. This device of Mr. Bowen's is intended to obviate this difficulty and to prepare the fruit for drying in an economical manner. The operation of pitting by this machine is very rapidly effected by mechanical means, no handling being necessary. It will handle large quantities of fruit in a short time and perfectly prepare it for the drying machines.

Bung Hole Lining.—G. H. Mixer, S. F. This patent covers an improved bushing or metallic lining for the bung holes of vessels and casks, and also an implement for inserting the bushing. These bushings, when thus applied, provide an air hole into which a wooden plug or bung may be driven without injuring the band stave or marring the edge of the hole. Heretofore these bushings have been made perfectly smooth in their interior and screw threaded on their exterior, so that a peculiarly constructed inserting implement was required to hold them, while they were being screwed into the opening, and being tapering on the inside, in cases where there was an inside pressure, as in beer casks, the bung was liable to be blown out. Mr. Mixer's improvement consists in constructing the bush with a shallow thread at the lower edge of the interior, and employing a screw plug inserter for turning it into the stave opening.

Gate.—J. M. Mendenhale, Livermore, Alameda Co. The invention relates to certain improvements in the construction of gates, and consists in the employment of two gates which run upon oppositely placed inclines, so that the gates may be separated and opened from these common centers of meeting by running up these inclines. It also consists in the combination with these gates and inclines of a series of cords and operating levers whereby the gates may be simultaneously operated by the person approaching the gate from either direction, by operating the lever without leaving the vehicle or animal, and they may be retained open until the passenger has passed through the gates, when they will close automatically. A lever opens the gates, which close by their own specific gravity at the proper time.

Wagon Axle.—Patrick R. Walsh. The improvements relate to a novel arrangement of wagon or carriage axles constructed in such a manner that the spindle ends can be taken off and replaced without disturbing the axle in its bed. An axle formed in one piece, if broken necessitates its entire removal from the axle bed and carriage, in order to be repaired, causing an expenditure of time and labor, and injuring the appearance of the carriage, paint and varnish being necessarily marred in the operation. By this invention in case of a break, which almost invariably occurs at the inner end of the spindle, the axle is taken apart at the joint, and a new spindle end fitted without removing it from the axle bed or carriage, thus overcoming the difficulties and objections of repairing a broken axle constructed of one piece in the ordinary manner.

Non-Conducting Waterproof Compound.—Alexander Sweeney. This invention is an improved compound for covering boilers, pipes and steam generators, or other articles from which it is desired to prevent radiation of heat, and at the same time to render the covering waterproof, so that it may be exposed to atmospheric influences, or washed down with a hose if desired. The compound unites itself so closely to the articles covered as to need no binding material, such as fiber, rope, or similar substances. This compound, we are informed, has been used on the boilers of some of the steamers of the Pacific Mail Steamship Company with very satisfactory results.

Bullion Shipments.—Since our last issue shipments of bullion from the prominent mines have been as follows: Northern Belle, July 15th, $8,024.20; Alexander, 18th, $3,799.13; Raymond & Ely, 14th, $3,999.42; Hillside, 17th, $11,639.80; Tyho Con., 15th, $4,657.55; Manhattan, 16th and 19th, $23,700; Star, 13th and 15th, $9,694; Christy, 22d, $4,671; Leopard, 23d, $5,900; Independence, 22d, $10,000; Tybo Con., 19th, $4,680.76; Christy, 23d, $5,759; Northern Belle, 22d, $11,532.66; Indian Queen, 15th, $3,558.83; Gold Hill, 25th, $8,660.

From Calistoga last week were shipped 160 boxes of sulphur and 150 flasks of quicksilver from the Sulphur Bank mine; 47 flasks from the Great Western, and 125 from the Napa Con. mine.

Ostrich Farming.

Ostrich farming has come into prominence of late, through the successful practice in South Africa. It was agitated as an industry fitted for our coast about two years ago, but we never heard that the suggestion was acted upon. If it has, and any one has the birds, we should like to know it.

In order to give our readers generally information concerning what is certainly a unique and interesting industry, we shall present some engravings showing the mode of ostrich growing in South Africa. The engravings are from plates which recently appeared in one of the English illustrated papers, being made in the first place from photographs taken on the spot.

The first man to go into ostrich culture on a large scale was Mr. A. Douglass, of Grahamstown, South Africa. Ten years ago Mr. Douglass obtained three wild birds, and afterwards eight more. As soon as he found they would lay in confinement, he began his experiments in artificial hatching. This attempt met with but little success for three years, till he invented the patent incubator, the success of which has become renowned. By its means he has increased the 11 birds to 900, and these and others, becoming dispersed throughout the colony, have made ostrich farming, next to wool and diamonds, the most important industry of South Africa.

Mr. Anthony Trollope's recently published book on "South Africa" contains the following description: "Mr. Douglass is, among the ostrich farmers of the colony, about the most successful, and the first who did the work on a large scale. He is the patentee for an egg-hatching machine or incubator, which is now in use among many of the feather growers of the district. Mr. Douglass occupies about 1,200 acres of rough ground, formerly devoted to sheep farming. The country around was all used not long since as sheep walks, but seems to have so much deteriorated by changes in the grasses as to be no longer profitable for that purpose. But it will feed ostriches.

"At this establishment I found about 300 of those birds, which, taking them all round, young and old, were worth about $150 apiece. Each bird fit for plucking gives two crops of feathers a year, and produces on the average feathers to the value of $75 per annum. The creatures feed themselves, unless when sick or young, and live upon the various bushes and grasses of the land. The farm is divided out into paddocks, and, with those which are breeding, one cock with two hens occupies each paddock. The young birds—for they do not breed till they are three years old—or those which are not paired, run in flocks of 30 to 40 each.

"Ostrich farming without the use of an incubator can never produce great results. The birds injure their feathers by sitting, and at every hatching lose two months. There is, too, great uncertainty as to the number of young birds which will be produced, and much danger as to the fate of the young bird when hatched.

"The incubator shown in the engraving on this page is a low, ugly piece of deal furniture, standing on four legs, perhaps eight or nine feet long. At each end there are two drawers, in which the eggs are laid with a certain apparatus of flannel; and these drawers, by means of screws beneath them, are raised and lowered to the extent of two or three inches. The drawer is lowered when it is pulled out, and is capable of receiving 15 eggs. Over the drawers and along the top of the whole machine there is a tank filled with hot water, and the drawer, when closed, is screwed up so as to bring the side of the egg in contact with the bottom of the tank. Hence comes the necessary warmth. Below the machine and in the center of it a lamp or lamps are placed, which maintain the heat that is required. The eggs lie in the drawer for six weeks, and then the bird is brought out.

"All this is simple enough, and yet the work of hatching is most complicated, and requires not only care, but a capacity of tracing results which is not given to all men. The ostrich turns her egg frequently, so that each side of it may receive due attention. The ostrich farmer must therefore turn his eggs. This he does about three times a day. A certain amount of moisture is required, as in nature moisture exudes from the sitting bird. The heat must be moderated according to circumstances, or the yolk becomes glue and the young bird is choked. Nature has to be followed most minutely, and must be observed and understood before it can be followed. And when the time for birth comes on, the ostrich farmer must turn midwife and delicately assist the young one to open its shell, having certain instruments for the purpose. And when he has performed his obstetrical operations he must become a nursing mother to the young progeny, who can by no means walk about and get his living in his earliest days. The little chickens in our farmyards seem to take the world very easily; but they have their mother's wings, and we as yet hardly know all the assistance which is thus given to them. But the ostrich farmer must know enough to keep his young ones alive, or he will soon be ruined; for each bird when hatched is supposed to be worth $50. The ostrich farmer must take upon himself all the functions of the ostrich mother, and must know all that instinct has taught her, or he will hardly be successful.

"The birds are plucked before they are a year old, and I think that no one as yet knows the limit of age to which they will live and be plucked. I saw birds which had been plucked for 16 years, and were still in high feather. When the plucking time has come, the necessary number of birds are enticed by a liberal display of mealies—as maize or Indian corn is called in South Africa—into a pen, one side of which is movable. The birds will go willingly after mealies, and will run about their paddocks after any one they see, in the expectation of these delicacies. When the pen is full, the movable side is run in, so that the birds are compressed together beyond the power of violent struggling. They cannot spread their wings, or make the dart forward which is customary to them when about to kick. Then men go in among them, and, taking up their wings, pluck or cut their feathers. Both processes are common, but the former, I think, is most so, as being the more profitable. There is a heavier weight to sell when the feather is plucked; and the quill begins to grow again at once, whereas the process is delayed when nature is called upon to eject the stump. I did not see the thing done, but I was assured that the little notice taken by the animal of the operation may be accepted as proof that the pain, if any, is slight.

The large engraving herewith given shows how the birds are herded and corraled. The birds run in large enclosures. The one where our view is taken is 3,000 acres, with a troop of 240 birds in it. Here, once a week, they are all hunted up by men on horseback, armed with large boughs of thorn, to keep the birds off, as many are very savage, and their kick is dangerous. One man will be observed in front, with a pack horse, loaded with Indian corn, to lead them.

The incubating room, as shown in the engraving, is located in a large building so constructed as not to be affected by change of weather. Here several incubators are at work; in one an egg can be seen just broken through. On the top of the machines are the birds' sleeping places, all heated. The drawers are represented as when lowered and drawn out, to show them; when again pushed in, they are lifted and fastened by large screws beneath them.

THE INCUBATOR ROOM AT MR. DOUGLASS' FARM.

CORRALLING THE BIRDS ON THE OSTRICH FARM OF MR. A. DOUGLASS, SOUTH AFRICA.

There were 97 deaths in this city last week.

Stock Operations vs. Mining.

From the misfortunes that have overtaken so many of our incorporated mining companies whose shares have been listed on the Stock Board, it has become with many a question whether this practice had not better be discontinued altogether. The moment these shares are so placed, they partake, more or less, of a speculative character, giving rise to antagonistic interests, which become thereafter active in their efforts to advance or depreciate such stock. According as one or the other of these interests obtain the mine is then run and its affairs administered, being worked, in the spasmodic endeavor to make a large bullion production, in a ruinously exhaustive way, or, on the other hand, so mismanaged as to cause financial embarrassment, put a stop to dividends and render recourse to frequent assessments necessary. Such has been the history of almost every mine whose shares have ever become the objects of this sort of traffic, many once prosperous or highly promising enterprises, and even entire districts, having been utterly ruined through the hedevilments of these conflicting interests. It is useless to deny these facts or to seek to break their force by quibbles about the convenience of this institution and the aid it has extended to practical mining.

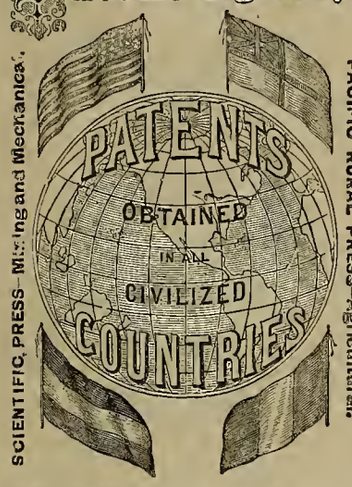
It is notoriously the case that companies who have abstained from putting their shares on the stock market, have, in the end, done better than those who have been allured into this species of gambling. This is even true not only of particular properties, but of entire classes of mining. None of our drift or hydraulic companies have offered their shares for sale through this medium, and yet these have shown themselves the most prosperous class of mines on the coast, these companies having managed their affairs with greater economy and in the end proved more successful than any others. Among the best examples presented in the department of quartz milling, are the Hites mine, the Sierra Buttes, Black Bear and the Plumas Eureka, none of which have enjoyed the advantages growing out of stock operations. How has it been with most of the companies who, the moment they were able to make a little bullion or a decent showing of ore, have hastened to get their shares registered at the Stock and Exchange Board? How have they prospered and in what condition are their affairs as a general thing? What of Pioche and Owyhee? What of Tuscarora and Cornucopia? What of the scores of claims about Washoe, and the other scores scattered over Nevada, Utah and Arizona, that have been represented in the mining share market, and for years have figured in our stock reports? What is their present condition and what are the majority of them doing in the way of producing bullion now?

Helping to develop the mines, forsooth! It has smitten them with death and dug their graves. Doubtless there are exceptions to this general truth. Doubtless there are cases in which developments have been helped on and the interests of properties promoted through these dealings in stocks. But these cases are rare. Generally such dealings have proved a detriment to the companies who have had anything to do with them, and we are speaking now solely of the effect these stock operations have exerted on the business of mining itself. What they have done to impoverish the community and debauch the public mind, what has been their influence, in fact, upon all classes of society, including the operators themselves, is another and more serious matter, but one that falling more especially into the province of ethical science, need not by us be further considered.

DEWEY & CO'S

SCIENTIFIC PRESS

Patent Agency.



Office—202 Sansome St., N. E. Cor. Pine, S. F

PATENTS obtained promptly; Caveats filed expeditiously Patent re-issues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washingtou; Examinations ordered and reported by Telegraph; Rejected cases taken up and Pat ents obtained; Interferences Prosecuted; Opinions ren dered regarding the validity of Patents and Assign ments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of thicoast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing.

The shrewdest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouragiug favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWELL—California.

Much Obliged, Etc.

PORTLAND, OREGON, June 26th, 1877.

DEWEY & Co., Patent Solicitors, S. F.—*Gents:* I am much obliged to you for courtesy shown me, and am much pleased with the manner in which you have done my business, and assure you, will cheerfully recommend you to my acquaintance needing such services. Hope to have a case again before long, of my own. I have been an inventor all my life, but let others reap the benefit, or had work stolen from me. Please have the extra copies of my patent, etc., mailed to me direct, and oblige

Yours truly, J. H. WOODRUM.

TESTING AND WORKING SILVER ORES.—This is the title of an illustrated work of 114 pages, for Miners and Prospectors, by Chas. H. Aaron, published by Dewey & Co. It is written for miners, in plain language, and with all necessary details in description. The author describes the different processes of roasting ores, the appliances, methods of testing ores, testing for a process, working samples, treatment of base metals, use of chemicals, leaching processes, different kinds of crushing apparatus, etc. This little work abounds with useful hints to miners and prospectors, and is written in a practical style. Price, post free, $2.00. Address, Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome St., San Francisco.

IONE VALLEY, Cal., January 20, 1878.

MESSRS. DEWEY & CO.—*Gentlemen:*—I received my patent last night, and was glad to find that you were so prompt in the matter. I am pleased to give you the credit due you for the faithful and honorable manner in which you have discharged your duty in getting my patent. I shall hereafter recommend you to the public as having discharged your duty with honor. Yours, etc.,

W. W. CARLILE.

THE EXPLORERS,' MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assayiug and metallurgy; containing 672 pages and 83 engravings. By J. S. Phillips, M. E. Price—cloth, $10.50; in leather, $12; postage 50 cents. Sold at this office.

ANY person receiving this paper after giving an order to stop it, may know that such order has failed to reach us, so that the paper is continued inadvertently, and they are earnestly requested to send written notice direct to us. We aim to stop the paper promptly when it is ordered discontinued.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued. wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus euployed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chloriuation Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cauuot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.50.

From A Patentee.

SAN FRANCISCO, July 1st, 1878.

MESSRS. DEWEY & CO., PATENT SOLICITORS.—*Gentlemen:*—On the first of June I made application for Letters Patent for an improvement on a fire-resisting and non-conducting compound through your Patent Agency, and was agreeably surprised to receive official notice that the patent had been allowed on the 15th day of June, in the unprecedented short time of fifteen days from the time it left here.

This is the seventh patent which I have procured. through your Agency, entire satisfaction being given in each case, and I shall take great pleasure in recommending your firm for reliability and promptness to all inventors with whom I may come in contact.

I have now two more cases ready, and shall make the application through your Agency.

Yours Truly, GEO. R. EVANS.

Gundlach's Microscopes.

ERNST. GUNDLACH

Would respectfully inform his friends and the scientific public generally that he, after having dissolved all connection with the "Bausch & Lomb Optical Co.," is continuing the manufacture of his well-known

MICROSCOPES and OBJECTIVES

On his own account, and that since March 8, 1878, all his articles have been and will be in future marked with his full name, "Ernst. Gundlach."

He also takes great pleasure in announcing that he has made several novel improvements in both Objectives and Stands, and that his new arrangements enable him to make a considerable reduction in prices.

Send for circular. Address,

ERNST. GUNDLACH,
Rochester, N. Y.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 20th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco.

ALL SIZES Hoisting Engines FOR SALE BY BERRY & PLACE

Double C. Reversible. 5½x12, 6x12, 7x12, 8x12, 9x14, 10x14; 7x12, 8x12, 9x14, 10x14

Market, head of Front Street, San Francisco.

SUMMER RESORT.

Exhiliarating Climate! Grand Scenery!!

☞Persons intending to spend a few weeks in the country during the summer months should stop at the Bridge House, on the South Yuba. Accommodatiou may be had for a few more boarders by addressing Mrs. R. H. CULBERTSON, Emigrant Gap. House only one mile from the station.

MINING INTEREST FOR SALE.

For a small amount, in several claims on one of the

RICHEST LEDGES IN ARIZONA.

Money needed for development. The ore will pay a handsome margin to ship to the city. Apply at this office.

FORTY ACRE FARMS.

In offering the Reading Ranch for sale in sub-divisions, I am disposed to accomodate the interests of all classes of desirable settlers, I therefore offer (besides large tracts) to sell farms (in favorable locations) of from 40 to 100 acres, at from $20 to $30 per acre. Semi-tropical fruits, corn, vegetables, and all kinds of grain and grasses, (including alfalfa,) will grow well without irrigation on these lands. The Oregon Division of the C. P. R. R., and a brisk growing town are near the land on the west, while the Sacramento river is near at hand on the east.

For further information of the Reading Grant, see my advertisement which appears from time to time in this paper. Address the proprietor on the premises,

EDWARD FRISBIE,
ANDERSON, SHASTA COUNTY, CAL

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,

(Of the San Francisco *Evening Post.*)

This volume is now ready. It is a large 12mo of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loop, at Tehachape Pass, on the S. P. R. R.; Yuma, Prescott, Phœnix, Florence, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains. Calabazas, in the valley of Santa Cruz; Corrumacion Peak, the Arivac Valley and the ruins of Casa Grande.

Also, numerous other engravings of ruines and scenes, comprising Mineral Park, Fort Whipple, Castle Doue, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the McCrackin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for $2 each.

HINTON'S NEW MAP OF ARIZONA,

Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, $2.50 each; in covers, $1.50 each. For sale by

DEWEY & CO.,
Publishers of the MINING AND SCIENTIFIC PRESS S. F.

PACIFIC RURAL PRESS,

A first-class 16-page Illustrated Agricultural Weekly, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Send for a sample copy.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:

One man, per day	$ 3 50
One man, per day	3 00
Wood, 1½ cords at $3	7 00
Cost of 20 tons	$13 50
Cost of one ton	67½

From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

BODIE and ESMERALDA.

Being an account of the Past and Present affairs of these interesting Mining Districts, with detailed descriptions of leading mines, including Maps and Illustrations, by Jos. Wasson.

Single copies, post-paid from this office, $1.

YOSEMITE FALLS HOTEL,

(Formerly Hutchinge')

YOSEMITE VALLEY, CAL.

CONNECTED WITH THIS HOTEL ARE

J. C. SMITH'S CELEBRATED

Hot and Cold Bathing Establishment,

Post Office, Telegraph Office

—AND—

Wells, Fargo's Express.

This is the only Hotel in this Valley with cottages separate from the main building and located immediately on the margin of the beautiful waters of the Merced river. Our

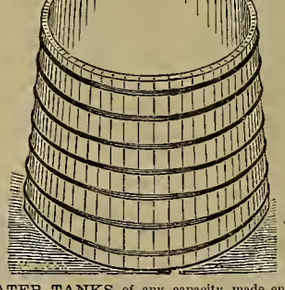
DINING ROOM,

Also on the river, looks out under shady trees and over green lawns, with a Grand View in a Direct Line of the Yosemite Falls, 2,634 Feet High.

INVALIDS AND PARTIES

Who cannot endure the fatigue of horseback riding, can see all the principal points of interest from the porches of this Hotel.

JOHN K. BARNARD, Proprietor.



WATER TANKS of any capacity made entirely machinery. Materials the best in use; construction excelled. Pan Staves, Tubs and Oak Guides for mining purposes a specialty.

WELLS, RUSSELL & CO.,

Mechanics' Mills, Cor. Mission and Fremont Streets

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

WANTED.

Good Live Business Men to sell the Excelsior Improved Letter Copying Book. No Press, Brush or Water used, copies instantly. Agents' Outfit, $2.50. Agents make from $10 to $15 per day. Address, EXCELSIOR MANUFACTURING CO., 47 La Salle street, Chicago, Ill. Incorporated Feb, 16th, 1877. Capital, $1,000,000. Exclusive Territory given.

MECHANICS' INSTITUTE.

13th INDUSTRIAL EXHIBITION.

SAN FRANCISCO, CAL., 1878.

The Managers have the honor to announce to the public that the Thirteenth Grand Exhibition of SCIENCE, ART and INDUSTRY, given under the auspices of the Mechanics' Institute, will open at the Pavilion on Market, Eighth and Mission streets, on

TUESDAY, AUGUST 13th, 1878.

Great and unusual attractions will be presented to visitors. Mining, Agricultural and other machinery will be in motion. Pacific Coast Manufactures, Minerals and products of the soil will be fully represented, beside many new and interesting novelties never before exhibited on this Coast. The

ART DEPARTMENT

Will be under the supervision of the San Francisco Art Association, a guarantee for excellence and completeness. Local Art will be specially represented, as also works of noted foreign artists, selected from the private galleries of this City. The

HORTICULTURAL GARDEN,

So popular heretofore, will be made still more attractive this year by the addition of many new features.

THE MUSIC.

Each afternoon and evening a first-class instrumental concert will be given by the best soloists and accomplished musicians of this City, with a daily change of programme of the best and most popular music.

No expense or pains will be spared by the Management that will add to the comfort or convenience of visitors.

Applications for space or information can be obtained from the Secretary, at the office, 27 Post street.

IRVING M. SCOTT, Pres't.

J. H. GILMORE, Sup't.

J. H. CULVER, Sec'y.

GOLDEN GATE ACADEMY.

A thorough training school for the best colleges. Also offers a solid, practical, business course, including bookkeeping. Location unsurpassed; methods most approved; health preserved and physical development secured by daily gymnastic and brief military drill. Preparatory department for lads in successful operation. Attention invited to methods and terms. Address for particulars,

D. P. SACKETT, A. M., Principal,

Oakland, Cal.

N. B.—The next school year will commence July 30th.

ICE! ICE!! ICE!!!

Ice at $1.00 Per Ton.

PICTET ARTIFICIAL ICE

COMPANY, (Limited).

Room 51, Coal and Iron Exchange.

P. O. Box 3083, New York.

ST. CHARLES HOTEL,

SANTA CRUZ, CAL.

JOSEPH BLOCH, - - Proprietor.

This popular House, having been thoroughly refurnished and refitted, is now open for the reception of guests as a

FIRST-CLASS HOUSE,

And in the character of its accommodations second to no interior Hotel in the State.

The Hotel Coach will carry passengers from all Trains and Steamers to the House

FREE OF CHARGE.

Two lines of Street Cars pass the Hotel to the Beach and Bath Houses.

Mill and Mining Machinery OF ALL KINDS FOR SALE by BERRY & PLACE

Mining Share Market.

The week opened with a lively and advancing market, the upward movement being especially noticeable in Ophir and Mexican, and certain of the north end stocks. Later, however, it appeared to be without stability, as, indeed, there was little calculated to impart to it either steadiness or strength. Only a weak and erratic market need in fact be looked for until tbe loug promised, delayed, ever imminent but ever postponed developments on the Comstock shall be in some measure either realized or abandoned as hopeless or regarded as tbings too far in tbe future to interest the present generation of stock operators. What was gained by Ophir and the north end stocks at the beginning of the week was afterwards lost, Gold Hill securities experiencing a spurt which in its turn also turned out to be short-lived and delusive. What with these bopes deferred and oft-recurring breaks the market seems to be staggering under a load that, with fast-coming assessments, tbreaten to break it down altogether. During the week California, for tbe first time in its history, sold below $10 per share, Con. Virginia having meantime sunk below $7.50, the lowest figure ever touched. Such a desperate decline in these once standard stocks has inspired the frequenters of the Bourse with a feeling of gloom and despondency, which nothing but the discovery of another monster bonanza can more tban partially dissipate. About the middle of the week Julia shares experienced a sharp advance, this being one of the mines in wbich it is expected a paying ore body will soon be developed; and tbat the chances for making such development are as good here as at any other point along the Comstock seems highly probable. Everywhere the miues on the Coast continue to yield their average quota of bullion. In some sections of the country and with certain classes of mines the production is unusually liberal, this being especially the case witb tbe hydraulic claims of California. With the most of these the working season is now near its close, having been one of large aud general success. The plan of operating in small companies and in a small way is coming more into vogue in this State, both because less money is needed for the purpose and because better results are reached in proportion to the amount of capital employed, than where mining is pursued by large companies. The earnings from mining operations are also in this case more diffused, tbereby aiding kindred industries and benefiting other classes hesides the miners themselves. The plan is, therefore, a good one, and as such will be likely to come into more general practice.

Guide for Quartz Mill Stamp Stems.

F. B. Picking, of Pioche, Nevada, has obtained a patent through the Mining and Scientific Press Patent Agency for an improvement in girt binders or guide frames of quartz mills, whicb keep the stems carrying the stamps in position, allowing them a vertical but no lateral motion. It consists in forming a metal hack plate which bolts to tbe girt timber, in or on which are formed dovetail mortices, and a metal hox formed square and tapering, having on one edge a dovetail tension, to fit in tbe mortices in the hack plate. In this metal box is a wooden lining or bushing, which is formed in two longitudinal valves, each half having a semi-circular groove, cut lengthwise down its inner face, so that wben they are in position iu tbe tapering box, tbe two grooves in tbe valves form a circular bole through wbicb tbe stamp stem plays.

Tbere are no bolts or fastenings to be removed and the hushing may be removed and replaced in a moment without tbe aid of tools. In case of a necessity of removing the stamp stems, the box holding the bushing may be taken from its dovetailed seat by sliding it up the stem, where it may remain, or it may be slid off altogetber. The back plate and box may be made of steel. The hardwood bushing will last a long time, and may be easily replaced when necessary.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

BOHEMIA S. M. Co.—July 22d. Capital stock, $10,000,000. Directors — Adolph G. Roden, Thomas McKeever, P. Von Loescke, S. Klein and G. Klaber.

GRASSHOPPERS have appeared in Hicks' valley, Mariu county. They are small, and as yet have done no damage.

Woodward's Gardens were never more attractive than at present. Besides three lions already mentioned, six monster living alligators, several iguanas and a boa-constrictor have just been added. New stars are constantly engaged for the Pavilion exercises. Rates of admission as usual.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Cohle, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

MR. W. J. WOODLEY, who took out a Canadian Patent some four years ago, is requested to call at the MINING AND SCIENTIFIC PRESS PATENT AGENCY OFFICE. Business of importance.

MODEL MAKER AND MACHINIST.—I. A. Heald, No 514 Commercial St., San Francisco, (fourth floor).

BUSINESS LETTERS should be addressed to the firm. Individual members are sometimes absent.

The Mechanics' Fair Daily.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the NINTH VOLUME of the MECHANICS' FAIR DAILY during the THIRTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Thursday, August 13th, 1878.

It will he of large size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official hulletin of the Institute.

Its columns will enhrace a large variety of important industrial and scientific informatiou, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will he employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhihition, the wonderful inventions, rich resources and rapid progress of our great Western commnnity.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its ahsorhing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle hy those who receive it freely at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive advertising and printing privileges, and will receive no advertising in the official catalogue and reports.

Our eight previous volumes have met with unrivaled sneeess and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent hy mail and otherwise to friends near and distant, giving the FAIR DAILY a more broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordiuary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonahle support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less henefited by such an advocate of the suhstantial advanecement of the grand and worthy industries of our Coast.

DEWEY & CO., Publishers.

Office, MINING AND SCIENTIFIC PRESS, No. 202 Sausome street, N. E. corner Pine, San Francisco.

APPRECIATION ABROAD.—We copy the following rom the *Mining and Monetary Gazette*, of London, England: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of *The Gazette*, the full text of the 'United States Mining Laws and Instructions, by the Commissioner of General Land Office, taken from our talented contemporary, THE MINING AND SCIENTIFIC PRESS, of San Francisco. The documents have now been issued in a handsomely bound volume by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very usefnl to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

Thie paper is printed with Ink furnished hy Chas. Eneu Johneon & Co., 509 South 10th St., Philadelphia & 59 Gold St., N. Y.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in thie paper, as the cheapest appropriate medium for the same.

Excelsior Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Potosi District, Lincoln County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Sixteenth day of July, 1878, an assessment of Twenty five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at the office of the Company, 304 Post street, San Francisco, Cal

Any stock upon which this assessment shall remain unpaid on the 29th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the Sixth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

FRANCIS P. DEVINE, Sec'y.

Office, 304 Post street, San Francisco, Cal.

Mariposa Land & Mining Company of California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the Tenth day of July, 1878, an assessment (No. 14,) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office No. 9 Nassau street, New York City, N. Y.

Any stock upon which this assessment shall remain unpaid on the Twelfth day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and the expenses of sale. By order of the Directors,

LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, 309 Montgomery street, San Francisco, Cal.

Orion Mining Company.—Location of Principal Place of husiness, San Francisco, California. Location of Works, Iowa Hill, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of July, 1878, an assessment, No. 2, of 70 cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 28 Sansome Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 9th day of August, 1878, will be delinquent, and advertised for sale at public auction; and unless payment is made before will he sold on Saturday, the 24th day of Auust, 1878, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors.

P. CONKLIN, Sec'y.

Office, No. 28 Sansome Street (up-stairs), San Francisco, Cal.

Seaton Mining Company.—Location of principal place of business, San Francisco, Cal. Locatiou of works, Drytown Mining District, Amador County, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-sixth day of June, 1878, an assessment, (No. 11,) of seventy-five (875) dollars per share was levied upon the capital stock of the corporation, payable immediately in U. S gold coin, to the Secretary, at the office of the Company, Room No. 58, Nevada Block, northwest corner Pine and Montgomery Streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of July, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the twenty-first day of August, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

JOEL F. LIGHTNER, Sec'y.

Office, Room No. 58, Nevada Block, northwest corner of Pine and Montgomery Streets, San Francisco, Cal.

Office South Comstock Gold and Silver Mining Company. Notice.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of Trustees and the transaction of such other business as may he presented, will be held on Monday, the 19th day of August, 1878, at two o'clock P. M. of that day, at the office of the Company. Transfer books will be closed on Saturday, August 12th, 1878, at the hour of 12 M. of that day.

J. M. BUFFINGTON, Secretary.

Office—Rooms 3 and 4, second floor, No. 309 California street, over Aetna Insurance office.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Seventeenth day of July, A. D., 1878, an assessment, (No. 4,) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of said Company.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, A. D., 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will he sold on the Tenth day of September, A. D., 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. J. W CLARK, Sec'y.

Office, No. 318 Pine Street, San Francisco, Cal.

Telegraph Copper and Silver Mining Company.—Principal place of business, City and County of San Francisco, California. Location of works, Gopher Mining District, Calaveras County, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of July, 1878, an assessment of three (3) cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at his office, Room 2, 523 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, 1878, will he delinquent, and advertised for sale at public auction, and unless payment is made before, will he sold on Monday, the Ninth (9th) day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

I. T. MILLIKEN, Sec'y.

Office, Room 2, 523 California street, San Francisco, Cal.

UNIVERSITY OF CALIFORNIA.

The August examinations for admission to the Colleges of Letters and of Science, will be held at Berkeley on WEDNESDAY, THURSDAY and FRIDAY, August 7th, 8th, and 9th, each day, at 10 A. M.

The University year begins August 8th. By order,

M. KELLOGG, Dean.

PAUL'S AMERICANIZED ARASTRA,

Will pulverize, amalgamate and concentrate with expedition, and amalgamate superior even to the Mexican arastra. Call and see it; just suits the times—cheap. Circulars forwarded on recipt of address.

KING — The Only SAFE BOILER.

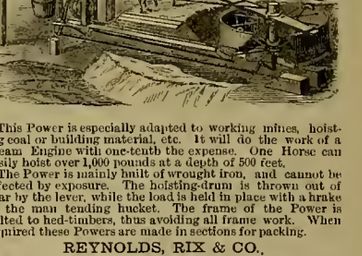
ENGINE. — SAVES One-half the FUEL Consumed by Others.

The engine is adapted to all the various industries in which small power is required. The engines are FIRST-CLASS, and are made from two to twelve horse-power.

The smaller sizes are especially recommended for irrigating land, driving printing presses, or manufactories. The larger sizes are being extensively introduced in small quartz mills, where their economy of fuel and portability especially commend them. Send for circular.

REYNOLDS, RIX & CO., Sole Agents,
18 & 20 Fremont Street, San Francisco, Cal.

MINERS' HORSE-POWER.



This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to hed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

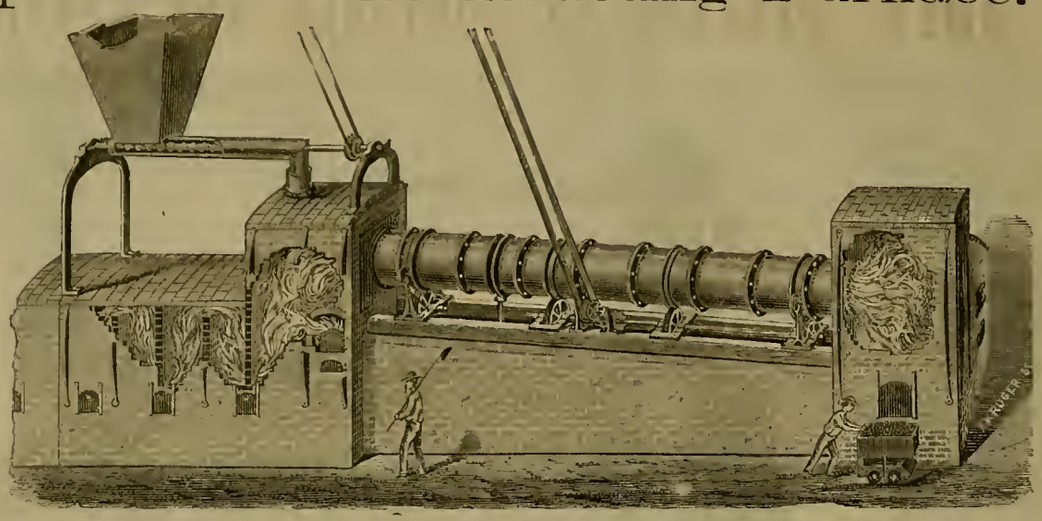
Howell's Improved White Roasting Furnace.



This cut represents the most improved construction of this unrivaled Furnace, the superiority of which, over all others as regards cost and capacity, as well as the economical and thorough oxidization and chloridization of ore, is now generally conceded.

In this Furnace, as covered by the Howell and White patents, are combined the three acknowledged requisites for the thorough and economical roasting and chloridization of ores.

First.—Continuous progression through and discharge of the ores from the furnace—while in the meantime they are, by being constantly showered through the heated air and gases within it, exposed in the greatest possible degrees to their reducing action.

Second.—Subjecting the ores to this showering process any length of time that may be necessary, according to the character of the ore, for its thorough reduction. In passing through the furnace it ordinarily falls about 1,000 feet, all the time in direct contact with the flame.

Third.—Increasing the heat on the ores as they are progressed through the furnace.

In this respect this furnace excels all others, as in none of them are combined all these essential requisites. It will chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade

The first cost, as well as the cost of operating it, is less than that of any other furnace of equal capacity.

It requires no especial skill in management that cannot be readily acquired by any one capable of conducting an ordinary silver mill.

We manufacture various sizes adapted to a five, ten or twenty-stamp mill, and will furnish plans by which any competent mill man can erect and operate it.

This furnace having the full or partial brick lined cylinder, embraces the devices covered by the patent to John Howell, as well as the original devices covered by the White patents. It has been erected and operated successfully at the following mines in California, Nevada, Arizona and Montana, viz: Camanche, Jefferson, Leopard, Utah, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry, Independence, Endowment and Alice.

At least ten of them are now in active and successful operation, in some cases reducing ores of the most refractory character.

These facts are a sufficient attestation of the merits of this furnace.

The undersigned, with Mr. John Howell, are the sole owners of the Howell patent, and they have perfected arrangements with him, and also with Mr. J. M. Thompson, who is owner of an interest in the White patents, and as such is possessed of as full and perfect rights and powers under the same as the patentee himself, by which they have acquired the exclusive right to manufacture these furnaces for the Pacific States and Territories. We hereby **caution** all parties against purchasing the same from any others but ourselves, or the said Howell or Thompson, as we shall prosecute all parties infringing upon the same. For particulars, price and terms, address

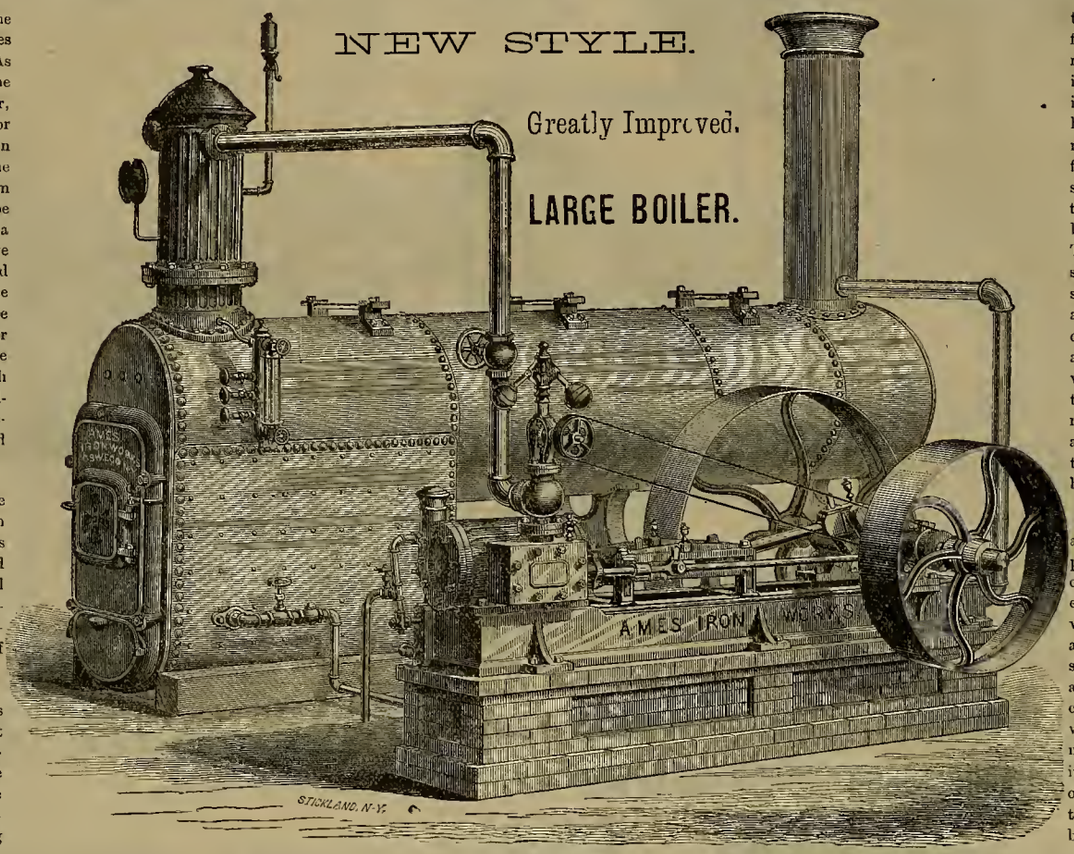
"AMES" CELEBRATED PORTABLE AND STATIONARY ENGINES.

This cut illustrates some of the important advantages of our "Portables." As regularly made, the Engine may, at pleasure of owner, be used on top of Boiler, or detached from it, as shown in cut, thus combining the adaptability of either form for *any location*. It will be necessary to send us a sketch, showing relative position of Engine and Boiler, and their distance apart, when intended to be run "stationary," in order to send with them suitable connecting pipes, which will be charged for according to extra quantity required over that furnished with the "Portables."

The Boilers are of the Locomotive Pattern, which requires no setting, and is made of such material and proportions and so arranged as to insure safety, durability, and the greatest efficiency for the amount of fuel consumed.

The shell and tube sheets of the Boiler are of the best Pennsylvania iron, of proper thickness to secure strength, while we take extra precaution, at an increased expense, of making



the furnace of the best solid fire-box plate, which has never heretofore been used in portables on account of its high price. We prefer, however, to make less money, and produce a really first-class article, safe and sure beyond peradventure, than to increase our profits by using cheaper material. The tube sheets are also selected from iron of proper strength and thickness, according to the diameter of the boiler. The Tubes are the best American lap-welded. Great care is taken in bracing the furnaces at the sides, as well as the top and bottom, in the manner adopted by the best locomotive builders.

We would call especial attention to the great improvement in the form of our Furnaces, obtained by extending around them a water space of ample size and curved form, its under side forming an ash pan, and allowing the water to circulate freely, thus preventing sediment from accumulating and adhering, as it does in the ordinary form of locomotive boilers, in that part of the furnace below the grate.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, AUGUST 3, 1878.

VOLUME XXXVII Number 5.

Beauregard's Clutch-Coupling.

The engravings on this page represent an improved clutch-coupling invented by Napoleon Beauregard of this city, half of the patent right of which is owned by Mr. B. P. Bruner, Superintendent of the Pacific Rolling mills. The clutch-coupling is intended for connecting and disconnecting the meeting ends of line-shafting. The improvement consists in providing an arrangement, in connection with an ordinary interlocking clutch, by which the parts of the clutch can be automatically thrown out of gear, and the two shafts disconnected while the shafting is in motion and under heavy strain.

The engravings show the device in detail, similar parts being correspondingly lettered. *A* represents a horizontal shaft which is connected with and driven by an engine, and, *B*, a horizontal shaft on the same line.

It may be stated preliminarily that this device is more particularly intended for use in combination with the line shafting of rolling mills, although it can be also applied wherever desirable. The nature of the work done by rolls of rolling mills frequently causes strains upon the rolls and shafting which necessitates an immediate disconnection of the coupling which connects the shaft. In the rolling mill the shaft, *A*, is connected with the power, and the shaft, *B*, transmits the power and motion to the rolls.

The permanent portion, *E*, of the clutch is attached to the shaft, *A*, and has one or more lugs or projections on its outer face, while the sliding clutch-box, *C*, which moves on the end of the shaft, has corresponding lugs or projections which interlock with the other projections when the sliding box is moved against the stationary part, in the usual manner of operating clutches.

On the outer edge portion of the permanent half, *E G*, are enclosed ratchet teeth as shown, the depth of which correspond with the hight of similar projections on the clutch.

The outer end of the projections on the sliding hand, *G*, are made inclined or sloping to correspond with the inclined edges of the teeth on the other hand when they are together. This band, *G*, rotates freely around the portion, *C*, of the clutch and independent of it, and is held in place by a strap, *F*, as hereinafter described. The hand, *G*, is inclined or beveled, as shown in Fig. 2, and the strap, *F*, is correspondingly inclined, so that when the strap, *F*, is thrown forward by the lever, *I*, it grips the hand, *G*, tightly and holds it in place.

This strap, *F*, slides loosely on the band, *G*, when drawn back, and in order that it may be slid in either direction, a bar, *D*, is secured to it. This bar, *D*, has a slot in its outer end, through which projects a rug attached to the sliding guide, *H*. This sliding guide fits in a groove in the clutch as shown, and then holds the strap, *F*, in place, at the same time admitting of a rotary motion. The slot in the bar, *D*, is extended as shown, so that the strap, *F*, may be slipped back or forth without being released from the guide, *H*.

Now when the two parts of the clutch are in engagement, the hand, *G E*, will accommodate itself to the projections and rotate with the clutch; but if the brake is moved so as to slide the strap, *F*, forward on the inclined part of the hand, *G*, the strap then grips the band, *G*, which will be held stationary while the clutch rotates inside of it. The continued rotation of the shaft causes the outer edges of the interlocking projections on the sliding portion of the clutch to move against the inclined edges of the ratchet teeth on the band, *E*.

The sliding portion of the clutch will then be forced outward and out of engagement with the projections on the permanent half of the clutch, so as to disconnect the two parts, the entire operation being accomplished while the shaft is in motion and under strain.

It may be seen by the engravings and foregoing description that this clutch is very effective in its action. In cases where there is a very heavy strain on the shafting, with the old style clutch it was frequently impossible to disengage the machinery from the power in case of urgent necessity. With this clutch the action is such as to be very effective and quick. A clutch of this style is in use on the 12-inch mill at the Pacific Rolling Mills, and it will shortly be used all through the mills.

A Chance to Exhibit Minerals.

Persons having specimens of ores or minerals to exhibit at the coming Mechanics' Institute Fair may send them directly to the Institute or to the MINING AND SCIENTIFIC PRESS, care of Dewey & Co. Specimens, consigned to our care, we will see are properly exhibited at the fair and held subject to the orders of the donors. Little is known of the variety of minerals in many districts on the coast, and this present offer might furnish many with an opportunity to do much good for parts of the country in which they may chance to be particularly interested.

In this connection, it may be well to mention that Californians, as a class, have the reputation of being not very enterprising in the development of the sciences. Noted lecturers from the East have left San Francisco in disgust, after discoursing on science for a few nights to empty benches. Californians are willing to stand quietly by and see Edwards' Pacific coast entomological collection, or some other such, packed up and shipped to the Atlantic, there to find liberal and eager purchasers. It is complained at the University that valuable California mineralogical specimens are sent indifferently past Berkeley to enrich the cabinets of Eastern collectors. Many such specimens of great value scientifically, if not in a money way, necessarily fall first into the hands of men that care little about the classification and cataloguing of the minerals of the State. A very little effort and trifling expense would be sufficient to place such specimens where they could be of great service—in cabinets to which scientific men have access. An opportunity like the above should be embraced. All that need accompany the minerals is the name of the place where they are found, and, if possible, the name of the mineral.

THE Minister of Commerce has informed the Central Committee of the Exhibition that he has decided to reduce the value of the gold medals, so as to double their number. There will now be 150 grand prizes and 2,500 gold medals.

Safety Brake for Cars on Inclines.

Henry H. Garrison, of Pioche, Nev., has obtained a patent through the MINING AND SCIENTIFIC PRESS Patent Agency for improvements on safety brakes on cars, being more particularly adapted for use on that class of cars used on inclines in mines, and which are lowered and raised by means of a wire cable or rope attached to an engine on the surface. It consists in the employment of a draw-bar to which the cable is attached, mounted on the axles at right angles to them in such a manner as to be movable backward and forward for a certain distance, and being firmly attached to one of the axles by a spring wheel draws it back when the strain on the cable is relaxed, and which admits of the draw-bar sliding forward until a shoulder strikes the axle when the cable holds the weight of the car. Engaging with this draw-bar by means of a slot on the bar is the long arm of a lever, the fulcrum of which is pivoted to the main frame of the car, the short arm of said main lever being cam-shaped and having projections on each end, on which rests the long arm of a grip lever, the two arms of these grip levers being held against the ends of the cam lever by a connecting spring at their ends. These grip levers are in turn mounted on the frame at right angles to the axles in such a manner as to admit of free backward and forward motion and so that their short arms, provided with clamp plates for the purpose, will grip the rails or sleepers in case the cable breaks, which action is accomplished by the spring on the draw-bar, aided by gravity, drawing it back when the cable is slackened too suddenly or broken, and thus moving the long arm of the main lever, which turns the short or cam-shaped arm so as to spread apart the long arms of the two grip levers and bring their other ends together so as to grasp the rail between them. Tension being brought on the cable draws out the draw-bar and spring, operating the main lever arm and reversing the whole action of the mechanism so that the spring connecting the long arms of the grip levers draws the long arms together, separating the short arms with the clamp plates and releasing the rail.

It will be seen that the device provides an effective means for preventing the escape of cars on an incline, in case the cable should break. It is positive in its action, holding tighter to the rails as the weight or friction is increased. With this attachment on the cars on inclines in mines serious accidents from breaking or surging of the cable could not occur, as the brakes would immediately check the onward progress of the car at the point where it was when the cable broke.

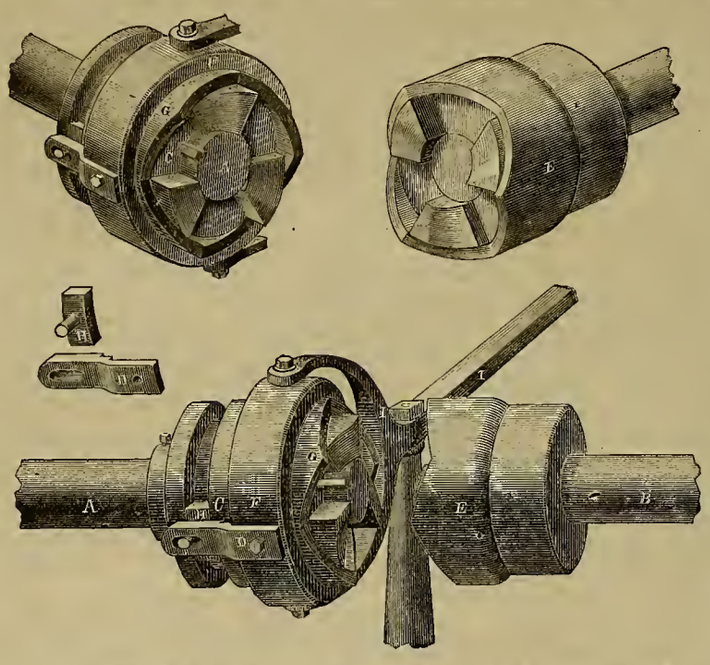

FIG. 1. BEAUREGARD'S CLUTCH COUPLING FOR ROLLING MILLS.

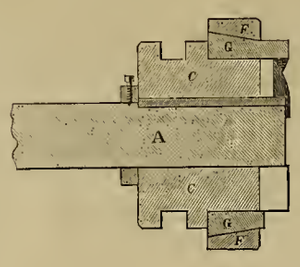
FIG 2.



Contemplated Railroads in Sonora, Mexico.

From Mr. J. R. Myres, a well known railroad contractor, formerly of Sonora county, and now a resident of Oakland, we gather a few facts with regard to the preliminary examination of routes for a couple of railroads, which will no doubt be built in the near future, and will extend into Arizona Territory. A party consisting of Mr. Myres, General Rosekrans and several other gentlemen, traveled by way of Fort Yuma, Cal., and Tucson, Arizona, to Hermasillo and the Allahranca mine in Sonora, by stage a distance from Tucson of 425 miles; thence by mule-back over the trails 130 miles further to the great Multatas gold mine.

This mine is near the river of the same name and is regarded as the best gold mine in Mexico. The party then returned to the Yuaka river, which they followed for about 40 miles, and then diverged to Guaymas, on the Gulf of California.

The railroad route examined was from the coal fields on the Yuaka river to Guaymas, 120 miles. The route was found to be practicable; and there is plenty of wood and water. At least one-half the distance is through as fine an agricultural country as there is to be found in the State of Sonora. The coal fields at the contemplated inland terminus are apparently of unlimited extent, and the mineral is of the finest quality of anthracite. It can be mined at very small cost. The building of this road will enable the owners of these mines to land a first quality of coal upon the wharves of San Francisco at a cost much below the price of the same article at the present time.

The party on their return from Guaymas made a preliminary examination of another route for a railroad from that place to Hermasillo, in Sonora, and thence to Tucson, in Arizona. The distance from Guaymas to the latter place is 420 miles. This road will intersect the road now being built by Thos. Scott, which has already reached Santa Fe, New Mexico, and is to be extended through Arizona to connect with the Southern Pacific or to be extended into California, perhaps to San Diego.

The route from Guaymas to Tucson, Mr. Myres says, passes through one of the best mineral and agricultural countries in Mexico. It only requires the construction of this road to facilitate the transportation of mining and agricultural machinery and the protection of a well established government to develop a very productive country. These enterprises are in the hands of San Francisco capitalists.

THE MECHANICS FAIR.—The fair will be duly opened as announced in advertisement on August 16th. Preparations are going on vigorously, and everything goes to show that this exhibition will excel all previous ones. Many changes have been made in internal arrangement of the pavilion and the exhibits will be made as attractive as possible.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS

Diameter of Hydraulic Pipe.

EDITORS PRESS:—Some parties here are preparing to fit up a hydraulic claim, and not having any more fall than they want, have heeu advised to use extra large pipe for tbe amount of water to be used, as by doing so the friction will be lessened and a good stream from tbe "Giant" obtained. The question now comes up what might be called extra large pipe, for in consulting those who claim to have experience in these matters, they do not seem to have any rule to be governed by, and speak from what they have seen or tried, nor do they agree.

If some of your readers would tell their ideas and give us their reasons, it would, I thiuk, he of much interest to many of us miners. Hoping that some of them will do so, I will state the case: Amount of water to he used, 500 to 600 inches, miner's measure. Length of pipe from sand-box to hank, 3,000 feet. Wanted, to know bow large pipe would be best, the head being 275 feet. The macbine to be wbat is known as a No. 3, witb four or four and one-half inch nozzle. Yours, etc., "GUESS."

Iowa Hill, June 15th, 1878.

It is hoped that some readers of the PRESS will "tell tbeir ideas" on this subject and "give their reasons." If it is intended in the above to state the following general problem: "What diameter of pipe is necessary to carry a given quantity of water per second, its length, and total bead heing known?" The writer may be referred to reliahle works on hydraulic mining. For the solution of the above problem the following rule bas been given:

(1). Multiply the head in feet by 5,280 and divide the product hy the length in feet. Call this A.

(2). Multiply tbe discharge in cubic feet per second by itself and multiply tbis product by 5,280. Call this B.

(3). Divide B by A.

(4). Extract the fifth root of this quotient.

(5). Multiply this root by .235.

Tbe result is the required diameter of the pipe in feet.

In the present case the terms of the prohlem are as follows:

(1). Quantity of water discharged per second in cuhic feet (a miner's inch heing equivalent to .0271 cubic feet delivery per second), = 600 × .0271 = 16.26 cuhic feet per second.

(2). Head = 275 feet.

(3). Length = 3,000 feet.

Following the above rule we have:

$$\frac{275 \times 5{,}280}{3{,}000} = 484 = A.$$

$$16.26 \times 16.26 \times 5{,}280 = 1{,}395{,}926.4 = B.$$

$$\frac{B}{A} = \frac{1{,}395{,}926.4}{484} = 2884$$

The fifth root of 2884 is, approximately, 5.

5 × .235 = 1.175 = diameter in feet.

The quantity of water discharged from a four-inch nozzle with a head of 275 feet may he calculated hy the following rule.

(1). Extract square root of the head aud multiply the result hy 8.03. Call the result A.

(2). Multiply A by the area of the mouth-piece, and the result will be the discharge in cuhic feet per second. The actual discharge is probahly 80% of this.

In the present case the discharge will he somewhat under 300 miner's inches.

The four or four and oue-half inch nozzle will not he large enough to use all of the 600 inches. At Cberokee the data are as follows: Quantity of water 500 to 600 miner's inches; head = 300 feet; diameter of pipe = 20 inches; diameter of nozzle = six inches.

Some men of experience in placer mining suggest that at the top of the hauk a 16-inch pipe he used for 100 feet or so, then a 14-inch pipe. Communications on the subject will he very welcome.

A Bean Harvester Wanted.

EDITORS PRESS:—There are growing upon this rancho and its adjacent horder not less than 2,500 acres of heans. To harvest this large amount in the short time hetween bean ripening and when rains may he expected, would require a small army of men if tbe usual method of hand-picking was resorted to. Is there not some machine already invented that would either cut or pull and therehy facilitate the harvesting? If not, some inventor should endeavor to supply such a patent need.

G. W. RICHARDS.

Lompoc, Santa Barhara County.

LITTON SPRINGS.—Tbis property has recently been purchased by Judge B. Lathrop, formerly of this city, now of Healdsburg, Sonoma county, and Geo. F. McPherson, of Oakland. The tract contained 2,700 acres, which has heen subdivided into 20 farms of 120 acres each, which are offered to tbe public at $40 per acre. Three hundred acres reserved, with the hotel, springs, cottages, etc., for sbareholders, a twentieth of which is deeded to each purchaser of a farm. Personal application can be made to Judge Lathrop at 316 Pine street, Wednesdays and Thursdays of each week, from 10 to 2.

"The So-called Heat-Wave."

On all sides the papers are lamenting the sad condition of our brethren east of the Rocky mountains, as reports bave been arriving day after day of the prostration of one city and tben another hefore the hlighting "heat-wave." The impression created by the reports has been tbat somewhere near St. Louis a great wave of heat originated—a veritahle *wave*, with a crest and hollow, that rolled along from city to city toward the east. Tbe crest passed St. Louis, and there the heat then gradually diminished, wbile Cbicago aud Cincinnati were snbmerged in tbe hillow. Meanwbile, the direction of advance of tbe "wave" was so nnmistakahle tbat, we are given to understand, New York could he warned heforehand to prepare for its arrival within a certain time. But, as reports continue to come, it begins to appear that the wave did not confine itself to an easterly course, hut went also south and west. It was as if the whole country ahout St. Louis were suhmerged in a tranquil sea of heat, and a stone thrown in somewhere near that city had sent ripples of the suhtle medium in circles to every point of the compass. After New York had suffered, the voice comes up from New Orleans; then, it may be, an Arizona paper announces tbat the "heat wave" bas reached Tucson; then Winnemucca complains; and then the "heat-wave" reaches Oregon. But in all this, happy California escapes.

Sucb a phenomenon as tbis was pictured to be naturally awakens a desire to learn, if possible, what this great "wave" is and how it originates. But investigation yields positively no information upon the subject furtber tban tbat the term "heat-wave," as used in these reports, bas merely a popular, figurative meaning, and conveys no scientific idea. "Heat-wave" in physics refers to tbose vibrations of the ether wbich constitutes heat itself. The "beat-wave" resolves itself into simply the unpleasantly hot season tbat visits the unlucky regions at tbis time every year. It is doubtful if there is evidence to show that this year bas heen more notable in the present respect than former years. Under the supposition that such evidence did exist, some one has suggested that tbe excessive heat was owing to the fact tbat the present is a year of minimum sun-spots. Clearly that would be difficult to prove even with the evidence in question at hand. But, as said before, tbis is wanting. The normal average temperature at St. Louis for the montb of June is, according to the Smithsonian statistics, 74°. This year the average was only 72.9°. The normal average for July is 78°. Tbis bas heen greatly exceeded the present year on individual days, hut it is quite possible that the average will not reach above tbe normal.

At present the writer is not prepared to say wbether or not the numher of sunstrokes this year has been greater than usual. If imagination can, as it does in many diseases, invite sunstroke and aggravate its effects, it is a wonder that there have not heen many more serious cases. For a reporter on a St. Louis paper relates that while, on one of the hot days, a reliable thermometer measured 97°, a numbcr of others in the neighborhood indicated 101°, 105°, perhaps as high as 107°. Tbe dissolute and the intemperate in the use of alcoholic stimnlants, it is said, succumb most readily to the effects of the heat. Is not this the case with every malady? However, it is elaborately explained tbat the heat favors malaria, and that the human system, saturated with alcohol, is most sensitive to malarial poison. Wbether this he true or not the records of the sunstrokes in the East hold up another warning lesson.

THE POCAHONTAS GOLD MINE.—This mine is located ahout five miles from Placerville in El Dorado county. It has recently heen purcbased hy Geo. F. McPherson, a capitalist of Oakland, and Albert Mack, of tbe city of San Jose; consideration, $26,000. A three-compartment shaft is being sunk, 6x14 fect, and timhered substantially, good steam hoisting works erected, an air compresser and Ingersoll drill put in place, and everything added necessary to the rapid and efficient development of the mine. There is also connected with the property a 15-stamp mill, with steam capacity for 25 stamps additional. This mine was originally opened in 1851 and worked for ahout 20 years, during which time the yield was ahout $1,500,000, although the appliances for raising and reducing the ore were not as perfect as now generally employed. The mine was worked through an incline, which reached the depth of 500 feet, cutting and exposing three ledges at different depths, varying in width from two and oue-half to four feet. They have now 21 men on the pay roll, and as soon as the shaft is down a proper depth to commence mining the ore, and the mill is started, employment will he given to many more.

NITRATE WORKS OF PERU.—The government of Peru has concluded negotiatious with the associated hanks of a final appropriatiou for nitrate works. Five million pounds sterling is to he devoted to the purchase, etc., and the government will have £1,000,000 left, which it is proposed to devote to the completion of the Chemhote and Cuzeo railroad.

Relics of the Gold Era of "'49."

A correspondent of tbe *Bulletin* writes an interesting accouut of a town of the Forest Hill divide in Placer county, in which he says: There are many parts of California worthy of the poet's pen and the artist's brusb—worthy a trip across the continent, to see which, from the excess of imposing scenery scattered so liberally on every hand, must remain content with tbe cheap pencil of the newspaper correspondent, and the hasty, perhaps impatient glance of tbe commercial traveler.

One of the finest rides in any land would he a tour of the Forest Hill divide, starting at Auhurn, emhracing the whole middle portion of the ridge between the uorth and middle forks of the American river, and ending at Colfax station on the Central Pacific railroad. The first three miles of the journey is down the grade of the river, which we cross on a Howe truss, just ahove the junction of the two forks. The Georgetown road has a fine wire hridge a few hundred yards below. To the '49er and his friends and children, who have listened to his winter evening tales of life in the mines and early days in California, and to the student who has learned of it from Bret Harte or the argonaut, the American is a classic stream. The gold lay in heaps, wbich waited in undisturhed security for the particular parties for which tbey were destined. No one hears of the ground that proved barren; of the hard life and poor fare; of fevers and accidents; of homesick hoys who would give all their prospective wealth to see their mother's face. Distance softens tbe hard outlines, and after these many years memory covers them with beautiful tints and graceful shades, like a purple snuset on the rocky Sierra. Tbe pictures of busy camps, of changing fortunes, of fuss and bustle, and in striking contrast to the solitudes which prevail to-day.

The American River of To-day.

A handful of Cbinamen turn the river and shake tbeir rockers where the banks were once crowded with cabins. An occasional bar is worked by wbites in a dry year. A new experiment is tried once in a while, hut these only serve to emphasize the desolation. Huge piles of rocks and boulders, banks cut deep into hills, ravines cut out as far as there was pay, show the enormous amount of labor spent in working out the gold. The product, instead of coming from bere, is now gathered among tbe clouds where the pioneer only saw buge mountain tops and cumbrous forests. He thougbt even if gold existed there no water could ever he made to reach it. Now we know that the deposits found in river beds and the thin snrface diggings were only crumbs which fell from tbe hoards hid for ages by some of nature's mysterous storekeepers, to be fought for and obtained by future generations only after an outlay of its weight in lahor and treasure. & From the bridge the vast wall of the canyon rises hefore ns like au alp. The grade winds around the points, which run out like tbe teeth of a comh.

The rise is very rapid and the river soon appears far below, and its fretful murmur is lost in tbe distance. The mountain up which we climh seems to be of no possible use. It can never be cultivated. It has no timber except a scattering growth of small scrub oak, and tbat cannot he got to any market. It may have mines somewhere in its rocky depths, hut the indications do not show it.

An old wagon trail on a steep and rocky point, which a driver nowadays would declare impracticable, is where in early days all the travel crossed between Hangtown and Illinois-town. The pilgrim who came overland by the Donner Lake road crossed here or went around hy Auburn and Sacramento to reach the rich diggings.

The track makes straight down hy Murderers' Bar, and with scarce a curve mounts up the Georgetown divide to Cave valley, with the apparent determination to be swerved hy no danger or to be detained by no labor in the fierce rush for the promised land. Fit emblem—that old, unused, washed-out road of the hrave and gallant men who climhed up and down. Fit reminder of thc howed and wrinkled heads whose years of usefnlness have past.

Ou the road to Forest Hill are scveral valuable ranches, the products of which are sold among the miues and mills ahove. Grizzly, Butcher and United States ranches are old and familiar landmarks, and we choose among them for lunch.

Volcanoville aud the mines of the California Water company scar the hrink of the great canyon. Forest Hill, Michigan Bluff, Yankee Jims, Sarahville, now Bath, and Todd's Valley are mining towns of some importance, hut not the camps they used to he. Large companies work as a wbole what was once owned in small lots, and the utmost economy in both numbers and wages is practiced, to the detriment of communities depending upon such localities. The outlet to all these claims is the Middle Fork canyon, whose great depths afford ample fall to work them to advantage. The water is led in flumes and ditches from reservoirs far up among the snowy summits.

Seeking a place to spend the night we turn at a sign-board "Sunny Soutb, two miles," and find our road very up and very down. Abandoning our vehicle we lead our beast into the town and escape the dangers of the descent as well as a hard pull out. Sunny South is a cluster of 20 houses huilt at the mouth of the Hidden Treasure tunnel. The mine is worked by drifting. Some beautiful specimens of pictured rock were given us. The company employs 50 men and works tbem at a handsome profit. Wood and timbers are cut on top of the mountain and hauled to within 1,400 feet of the tunnel, wbere tbey are thrown into a chute, down which tbey fly like cannon balls. The teams are thus saved the hardest part of the road. Tbe towu is clinging for dear life to the soutb slope of tbe divide. It is not so favorably located for anytbing as for the inspection of the foundatious of one house from the roof of the next.

Descending and Ascending.

In a conspicuous place hy the side of tbe road stands a guide board bearing the laconic legend "Damascus—down damn big bill one mile." Partaking of tbe spirit of tbe hardy miner, who makes a joke of sore feet aud shaky knees, we again left our team and the scramble began. Skipping, shuffling and tumbling, we twisted down the zigzag trail in three minutes and came up in three bours. Damascus uestles near the head of Humbug canyon and lies on tbe north side of the ridge ahout opposite Snuny South. It is dependent on the Golden Gate mine, which is on the same lead with Hidden Treasure, hut much older. It is divided into shares owned hy the miuers. Each man is obliged to work his own share or put a man in his place. If he sells his claim the company pays the purchaser $1.50 per day out of the proceeds, the balauce going to pay the seller. The President, Secretary and Superintendent work their daily shift. Our road lies past the Canal Company's reservoir, whicb is in the center of a fine body of sugar pine, several miles in extent. On tbe head of Shirttail canyon aud hranches, a saw mill is at work cutting it into lumher. We get an occasional glimpse tbrough the trees of the almost bottomless canyon on our right, which we must cross before long. We gaze into its deptbs like a small man trying to fathom the mind of a great one.

Iowa Hill.

Iowa Hill bas seen better days. It is shahby geuteel. It is perched on the edge of a high bank that has been washed out, in plain sight of thc Ceutral Pacific, helow Gold Run. The mines are of gravel, and have a good depth. The prospects were very good tbis spring. The mines were nicely opened, aud preparations bad been made for a hig run, but the water failed suddenly, and tbe yield did not pay expenses. Too much rain and uot enough snow was the trouhle.

AMERICAN COAL IN EUROPE.—The United States Consul at Genoa reports that important results are likely to flow from the recent effort of a Philadelphia coal company to introduce American anthracite coal into the non-coal-producing regions of Southern Europe. Two cargoes have been received during the past quarter, and the experiment, which at first threatened failure, has proved a gratifying success. Whcu first put on the market the highest hid was 22 francs ($4.25) per ton—an amount insufficient to cover freightage from New York. On its becoming knowu that the coal was well adapted for smelting purposes, the price at once advanced to 40 francs ($7.72) per ton, which covers cost and freight, and leaves a fair margin for profits. Heretofore, English coke, selling at 60 francs ($11.58) a ton, has been almost exclusively used by Italian iron founders; hut as American anthracite, on trial, yields equally good results, if not better, there is no reason why it should not commaud the market. Over 200,000 tons of English coke are annually consumed in tbe Mediterranean basin. For this trade Amcrican anthracite hids fair to become a successful competitor.

SUPERSTITION OR SCIENCE?—This is an age of enlightenment, yet old superstitions cling fondly about us. It is related that but a few years ago a man in one of the northern counties of this State refused to kill his pigs at a certain season, hecause he said the moon was not in the right sign of the zodiac for killing pigs. In this particular instance the poor man came to grief, for a season arrived when, right sign or wrong sign, he was compelled to kill his pigs; the weather turned out very warm and his pork was ruined. Tbe question of superstition confounded with science was suggested hy noticing in a Nevada paper that in one of the towns, a few days ago, the people were half convinced that on a certain day a cloud would burst over them. Their prophetic conviction was hased upon the fact that said day was the anniversary of a cloud-burst that overwhelmed the town a year ago. We have no news of a realization of their fear. A terrific cloud-hurst has, however, deluged Tucson, Arizona. In the same spirit San Franciscans used to watch with dread the approaching anniversaries of our morc serious earthquakes. It is as if the study of the heavens had trained the human mind to expect every pbenomena to move in cycles.

THE MICROSCOPE IN ROCK SECTIONS. — M. A. Michel Levy recently contributed to the *Annales des Mines* a valuable paper upon the use of the polarizing microscope, for the determination of mineral species by small sections. The investigations of Rosenbusch, Fouquee, and Descloisseux, altbough all emhraced within the last decade, have already hecome classical. Levy tahulates their conclusions, and gives a complete mathematical analysis of the angles of extinction presented hy the sections of a zone, together with a practical application to the study of the principal monochinic minerals, and of some triclinic feldspars.

MECHANICAL PROGRESS.

Knocking in Steam Engines.

Mr. Stephen Roper, mechanical engineer, gives the *United States Miller* an article on "knocking" in steam engines, which will be interesting to our readers. We condense as follows: The most frequent causes of knocking in steam engines are lost motion in the cross-head, wrist and crank-pin boxes; looseness in the pillow-block or main bearing boxes; looseness of the piston rod or following plate; the crank-pin or crank-shaft being out of line with the cylinder; or the wrist-pin, crank-pin or main bearing journal being worn oval; the slide valve having too much or not enough lead; the exhaust opening too soon or too late; the valve being badly proportioned or the exhaust passage outside of the cylinder being contracted.

Other causes are shoulders being worn in each end of the cylinder, in consequence of the packing-rings not traveling over the counter bore at each end of the stroke; or shoulders being worn on the guides, resulting from the cross-head shoes not overlapping them, when the crank is at the dead center; the piston not having sufficient clearance at either end of the cylinder, in consequence of its being altered by taking up the lost motion in the boxes; there not being sufficient draft in the keys to take up the lost motion in the connecting-rod boxes; the packing screwed too tight round the piston rod; excessive cushioning, resulting from the leaky condition of the piston, which allows the steam to occupy the space between the cylinder and piston head, as the crank approaches the center, thereby subjecting the engine to an enormous strain, as at this part of the stroke the fly-wheel is traveling very fast and the crank moving very slowly; or lost motion in the connection by which the slide-valve is attached to the rod. Engines out of line frequently knock sideways at the half stroke, but most generally at the outward or inward, upper or lower dead center, as these are the points at which the greatest strain is thrown on the bearings, in consequence of the direction of the connecting-rod having to be reversed. The foregoing causes of knocking in engines constitute the principal ones.

The knocks arising from lost motion in any of the revolving, reciprocating or vibrating parts of an engine may be located by placing the finger on the part while the cross-head is being removed back and forth on the guides by the starting-bar. But knocks induced by the valve opening or closing too soon, by a contraction of the exhaust, or by the valve or valves being improperly set, are the most difficult to discover, as they are different from those induced by lost motion, the sound being a dull, heavy thud, in many instances causing the engine building and even the foundation to vibrate at every stroke. While an intelligent and careful search will in most cases result in successfully locating the knock, some will for a time baffle the most expert engineer. Instances are not uncommon in which weeks have been devoted, engines taken apart and put together again to find a knock, which, when finally discovered, perhaps turned out to be caused by a loose crank-pin, follower-plate or key in a fly-wheel. It not unfrequently happens that after every other means have been resorted to, the indicator has to be applied in order to determine the precise location of the knock or "thud."

From whatever causes knocking in engines may arise, they are a nuisance, which sounds harshly, not only to engineers, but to all who have an ear for natural mechanics. Nothing perhaps makes the intelligent engineer feel so cheap as to be found in charge of an engine that knocks, as lookers-on are not always capable of deciding who is the fault, the engine or the engineer.

INTERESTING ARCHÆOLOGICAL DISCOVERIES.—According to a Washington correspondent, Professor Baird, of the Smithsonian Institution, is preparing to send, within a few days, one of the scientific specialists in his employ into Virginia, to prosecute the archæological investigations begun under the auspices of the Institution. The region of the investigation lies in Amelia county, about 50 miles south of Richmond, where there have been discovered quarries of soap-stone, or steatite, which appear to have been worked by the aboriginal inhabitants of the continent. Extensive traces have been found of these ancient quarries, out of which were procured the pots and various domestic vessels used by the aborigines of this region. A great number of specimen articles have been obtained already and brought to Washington. The examinations which have thus far been made prove that the quarries were abandoned at least 400 years ago, there being found in them no vestige of iron or other metal implements.

AN ELECTRIC TARGET.—A target which by means of electricity shows instantaneously upon another target set up at the firing station the exact spot where a bullet strikes, and thus does away with the necessity of employing a marker to signal the result of each shot, has been recently perfected, after years of labor, by a Swiss locksmith. The exact details of the target in its latest form are not yet published, but a description was given a short time ago in a Swiss paper, and also in an Australian military periodical, of a target on the same principle, which was successfully tried last year. In this target the face is divided into a number of concentric rings, and each ring again is divided by two lines drawn right across the faces and crossing each other at right angles at the center. In each of the subdivisions of the target at the firing station a small hole is pierced, and when a bullet strikes the distant target a number at once appears in the hole in the corresponding subdivision of the target near the shooter, or should the ball strike upon one of the lines dividing the face of the target, numbers are shown in both the adjacent subdivisions. In the trials made with the target the apparatus worked perfectly during the eight days for which the firing was kept up; the only accident which happened being that once the electric wire was cut by a bullet.

The Importance of Dipping Vertically in Tempering.

In his articles on the cooling of steel during hardening, in the *Polytechnic Review*, Mr. Joshua Rose calls attention to the importance of dipping vertically and not otherwise. He says: The splitting or cracking of steel occurs during the cooling part of the hardening process, and is to be easily avoided even with the most unfavorable of steels, if the conditions of cooling are made to conform to the form and size of the article. The cooling is, in a large majority of cases, performed by dipping the heated steel in water; and the manner in which the dipping is performed may be made at will to crack, warp, or straighten the article.

The instant the surface of a piece of red hot steel enters the water, a rapid contraction of the submerged portion takes place, and unless this contraction is kept equalized to suit the shape of the article, the side or part most contracted will bend hollow, causing the diametrically opposite metal to bend to accommodate the inner curve. Suppose, for example, we heat a piece of steel, an inch square and 12 inches long, to a red heat, and dip it *slowly* in water, so that one side of the square will strike the surface flat and evenly; then that surface will contract while the diametrically opposite or upper surface will remain expanded; the lower face will curve to a concave, the upper one to a convex. If, then, such a bar were curved during the heating process, we may help to straighten it by dipping it slowly in the water with its convex side downward. If it was bent at one end only, we may dip it at that end first, diagonally and with the convex side downward. If, however, we dip it with its length lying either diagonally or horizontally, we are apt to warp it, no matter how quickly it may be dipped.

From these considerations we may perceive how important a matter the dipping is, especially when it is remembered that the expansion which accompanies the heating is a slow process compared to the contraction which accompanies the cooling (although their amounts are of course precisely equal), and that while unequal expansion can only warp the article, unequal contraction will, in a great many, or, indeed, in most cases, cause it to crack or split.

AN AUTOMATIC ORGAN.—The latest attempt to elicit music wholly by mechanism seems to be the "Needham Musical Cabinet," of which we find enthusiastic descriptions in Eastern exchanges. We are told that "Any child that has the ability to work the pedal of a sewing machine can produce all the music, with the aid of the instrument in question, that can be rendered by the most skilled of professional performers. The instrument is called the 'Needham Musical Cabinet,' and when it is closed resembles an ordinary parlor organ. The register consists of reed action and bellows similar to the ordinary organ, but somewhat smaller. The register consists of 39 reeds, but has no finger board. Rolls of perforated paper, about 18 inches wide, properly placed in position, suffice to shut off all the notes except those which are to be sounded, hence any tune can be played and in all its parts. When a piece is played it must of necessity be rerolled upon the cylinder from which it has been played before it is ready for repetition. The mechanism of the instrument is such that the work of rerolling can be accomplished while another piece is being rendered. It is a marvel of simplicity, and it may be doubted whether human hands can be trained to equal it in producing combinations of harmony."

STEAM BOILERS.—The improvements suggested by Mr. E. de Loriere, of Chelsea, consist in constructing an internally fired boiler, with flues oval at the front and cylindrical behind. This tubular flue is furnished with a number of vertical tubes, diminishing in diameter from the front to the back, so that the size of the tube may be proportionate to the quantity of heat remaining to be taken up. The fire-bars are used slightly inclined from the front to the back of the boiler. The invention was provisionally specified, but the patent was not further proceeded with.

AMERICAN LOCOMOTIVES FOR AUSTRALIA.—The Baldwin Locomotive Works at Philadelphia have received an order for two large and powerful locomotives for the New South Wales Government railways. The Baldwin company turned out one engine daily during June.

SCIENTIFIC PROGRESS.

The Life of the Mammoth.

Prof. Henry A. Ward, of Rochester, who recently mounted the celebrated Stuttgard mammoth, speaks as follows, in a letter to the Rochester *Democrat*, of the habits of the animal: But by far the greater mass of the great herds have left us nothing except their bones, teeth and tusks. The number and volume of these remains, which are dispersed over this entire region, is something almost incredible. Certain islands in the Siberian sea have the soil crowded full of them. This is particularly the case at the Laichovian Isles, north of the mouth of the River Seva. The tusks are so numerous and are in a state of such excellent preservation that they form an important article of commerce and are annually shipped in large quantities to Russia and to England, then to be employed by the ivory turner in the same works as is what may be termed the living ivory of Asia and Africa. The preserver in Siberia of these countless large bones, buried under ground and frozen in the ice, has long been a wonder to the inhabitants of the country, who had no reasonable explanation of their source or origin. With absurd credulity they attributed them to a gigantic mole, which they thought burrowed in the ground, living on roots and only appearing at the surface during the darkest nights. To this creature they gave the name of mammoth, which in their language is a term applied to any burrowing animal. This name has been universally accepted in Europe, but limited to the species studied by Cuvier, and described by his friend Blumenbach as *Elephis primigenius*. Cuvier showed the near relation of the mammoth to the modern Indian elephant, its degenerate successor, while another fossil species called *Elephis priscus* was more closely allied to the African animal. Bones of these and still a third species of mammoth are abundant in nearly every part of Europe from England to Spain and Southern Italy, although, strange to say, they become less and less abundant as we approach southern lands, the present home of the race.

In short, the mammoth was once an inhabitant of northern temperature and frigid zones; now his descendants inhabit the tropics. Its remains occur chiefly in beds of gravel, clay and other loose material of the post-pliocene age. In Europe, at least, it seems to have lived coeval with early man. In the bone caverns of England, France and Germany, those great charnel-houses of early animal life, there are found scores and hundreds of the remains of the mammoth commingled with those of the rhinoceros, hippopotamus, anrochs, cavern bear and other animals now quite extinct, or living in other continents. It is clear that the mammoth did not themselves crawl into these caves, often with an extremely narrow opening, and die there, nor do the surroundings allow the idea that they were brought there by the flow of waters. In many cases the abundant marks of teeth and gnawing of the bones show that they were dragged to the cave by wild beasts who made it their den and fed upon them. But in a few special cases the cavern has been the home of early men, who brought there remains of the animals which they had hunted and killed. In these caves there are found, with those of other animals, many bones of the mammoth, and of these every long bone, as those of the leg, has been carefully split open to obtain the marrow from the central cavity. Mingled with these bones are found here and there the flint knives and stone hatchets which served as utensils at these early feasts. On a tusk of a mammoth found in one of these caves in Dordogna, in Southern France, was a rude engraving of the animal itself, scratched thousands of years ago, with the sharp point of a flint. These troglodytes are now no more. They and their giant neighbor, the mammoth, have perished one after the other in the lapse of infinite ages by those changes of circumstances in the organic and inorganic world which are always in progress.

ANCIENT GEOGRAPHY.—Some stir was lately produced by the discovery, in the Lyons library, of a globe of 1701, in which the Zaire Congo was represented as flowing from a large lake westward to the Atlantic, much in the direction shown by Stanley. M. Costamhert remarks in a recent number of *La Nature*, that not only in this case, but in all old documents from the fifteenth century such representations occur. The knowledge acquired was doubtless due to the Portuguese, who, from the fifteenth century, repeatedly crossed the African continent, both from west to east and from east to west. They went rather as merchants than explorers, and were often, no doubt, ill-informed; yet they were able to give pretty precise information about the center of Africa. In most of those old maps the Congo is shown as flowing in a nearly direct line from Lake Zaire or Zamhra to the Atlantic. On one Spanish globe, however, probably dating about 1530–1540, the river appears as rising from a lake, flowing northward, describing a large curve north of the equator, then turning west-southwest toward the Atlantic, more nearly as Stanley represents. Some of these maps are reproduced in *La Nature*, May 4th, and are well worth examination.

RECORD OF THE YEAR'S PROGRESS.—Prof. Spencer F. Baird's "Annual Record of Science and Industry," lately published by Harper & Brothers, of New York, has been received through Roman & Co., of this city. This publication, which has been issued each year since 1871, furnishes in compact form a record of the leading scientific and industrial achievements for the time under review, and is invaluable to the scientific and general reader, as it enables him to survey the field quickly and pursue any item of progress which interests him. It gives the specialist an opportunity for a hasty glance at what other specialists are accomplishing in the several lines of research. In this volume a change has been made in the plan of the book. The different departments of science and industry are reviewed by eminent men, recognized as authority in their distinctive fields, and thus essentials are rightly chosen and truthfully presented. Among these writers of summaries are Prof. E. S. Holden in astronomy, Cleveland Abbe on terrestrial physics, Prof. G. F. Barker on physics and chemistry, Prof. E. S. Dana on mineralogy, Dr. T. Sterry Hunt on geology, S. H. Scudder and Francis M. Green on geography, Prof. Hamilton L. Smith on microscopy, Prof. Otis T. Mason on antrophology, Prof. A. S. Packard on zoology, Prof. F. G. Farlow, on botany, Prof. W. O. Atwater on agriculture, Dr. W. H. Wahl on engineering and technology, etc. These names are a guaranty of accuracy. The volume is carefully indexed and is a model of condensation.

BOTANICAL STUDIES.—Prof. Meehan, in the *Independent*, remarks that there are few scientific fields that afford more scope for original and interesting observation than the botanical. There is hardly a day but some student strikes on a novel feature, and it will be many years yet before we shall have discovered in it all that is to be known. In an English paper recently we have an interesting account of the productiveness of bulbs. Some yield an immense number of offsets, while others reproduce very slowly. In the case of one variety of tulip, called the "Goldham's Mary," only one new bulb is made every year. Many varieties of tulip "think nothing" of yielding a dozen or more. Among the Gladiolus of our garden the same was found to exist. From one variety, called "Brenchliensis," the observer could get a thousand young bulbs in a half-dozen years, while many will not give half a dozen new bulbs a year. There is, of course, a reason —some law governing this productiveness, and which, when discovered, will throw light on many other problems; but the reason has not been made clear yet.

DISCOVERY OF A SALT MINE.—A New York dispatch, June 25th, says: "A remarkable discovery of pure rock-salt has just been made in this State, near the village of Wyoming, forty miles southwest of Rochester, on the Rochester and State Line Railway. On Tuesday, last week, a laborer, employed by a Mr. Evest, was sinking an oil-well, when, at a depth of 1,200 feet, the drill struck a stratum of rock-salt 100 feet thick. The mine is supposed to cover a large territory, and that the salt marshes of Syracuse drain the bed. The salt has been examined by a scientific gentleman, and he says that it is the best rock-salt. Those familiar with salt say that this salt just discovered is pure enough to be shipped to market directly from the mine without receiving chemical purification. There are but few extensive mines of pure salt in the world. There is one in Valencia, one in Poland, and one in Armenia, near Mount Ararat."

A NEW ANIMAL POPULATION.—The *Polytechnic* announces that Prof. E. D. Cope has recently discovered, in a number of different regions from Illinois westward, the remains of a very peculiar and prolific population of lower animals, which inhabited North America during the Permian period, or that which immediately succeeded the Carboniferous. He has determined some 50 species, mostly reptiles and batrachians, some of which are of large size. They are all peculiar in the imperfection of the vertebral column, which retains a large proportion of the fetal cartilaginous cord and which is segmented in various peculiar ways. Superadded to this were limbs and teeth of a high order of organization. In this fauna were both herbiverous and carniverous forms. An account of these interesting discoveries will appear in the *American Naturalist*.

HATCHING SILKWORMS EXTRAORDINARY.—An extraordinary statement is made by *Galignani*—viz., that M. Duclaux, Professor of Sciences at Lyons, has discovered a method of hatching silkworm eggs at will. If, when the eggs are not more than two or three days old, they are rubbed with a brush, subjected to the action of electricity, dipped for half a minute in concentrated sulphuric acid, or chlorohydric, nitric, acetic, or tartaric acid, they will hatch out, and, as the mulberry is in full leaf, two crops of worms are thus obtained in one season. Immersion for a few seconds in water heated to 122° Fahr. is said to be equally efficacious. The worms from the artificial hatching are said to be hardier than those reared in the ordinary manner.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

GOVER.—*Ledger*, July 27: Everything moves along prosperously about the Gover. Superintendent Palmer expects that the new shaft will reach the 700 level within a week. The mill is running on average quartz from the 600 and 700 levels.

BUNKER HILL.—The mill is well supplied with excellent ore from the 230 level. Average output of gold is from $10 to $13 per ton. The shaft has only been explored to the depth of 380 feet. The managers have determined upon the erection of a 20-stamp mill.

VOLCANO ITEMS.—J. Grieshack is putting up hoisting works on his mine near Mace's mill, to he run by the same power that runs the arastra. Another quartz vein has heen uncovered near Volcano, in the vicinity of Robinson's claim. Stewart's mill is running on Downs' rock. The indications point to a splendid yield. Work has been resumed on the McCreevy claim. This consists of a small quartz streak, three or four inches wide, but carrying a heavy perceutage of gold.

VAUGHIN MINE.—*Dispatch*, July 27: The Vaughin (previously the Bismarck) is now in a fair way to be thoroughly prospected and developed. The old shaft is being cleaned out; this done machinery will be put up and the shaft sunk to a depth of about 300 feet, drifts being run in the usual manner.

ITEMS.—During the week several ounces of gold, including pieces worth several dollars each, was washed out from the dirt under a hotel in Fiddletown. The Volcano tunnel is in 1,100 feet; rock hard as steel. Rock estimated at $40 is going to mill from the Downs mine; rock estimated at from $75 to $100 per tou is being taken out.

BUTTE.

MOUNTAIN SPRING TOWNSHIP.—*Mercury*, July 26: Creek and ravine miuing is about suspended for the season for the want of water, but there is much activity in river mining. In the South Fork of the Feather, the following companies are at work: Woodman, Kneen & Co. are putting in a dam and flume at a point where the Mooretown wagon road crosses the river. Craudall & Co. are working the bar just below and opposite Stringtown. At the bend of the river a large company of Chinamen are at work. A. Price is opening a claim about half a mile below the hend, and Mr. Ury has one opened ahout half a mile helow Mr. Price's. These claims are all helow the F. R. &. O. Water Co's head dam. Above the dam are several companies at work, but I do not know their names or the figures they have made. Of the above mentioned companies, Mr. Ury is the only one tbat has his claim opened. The others will be a week or ten days finishing their flumes and getting their machinery in working order. On the South Branch of the Middle Fork of Feather, several large companies of Chinamen are at work in the river hed. There does not seem to be much going on in the Middle Fork. Quartz mining is beginning to attract considerahle attention. Oro company's tunnel has heen driven into the hill nearly 600 feet. The Electric mill is now running ou quartz taken from a newly opened lode with very good success. E. W. Wagoner has re-located the Crystal Hill lode and has found prospects that he considers will justify him in erecting a mill.

CALAVERAS.

ENORMOUS YIELD OF GOLD.—*Chronicle*, July 27: We have returns from the richest quartz we ever heard of being worked. It is on the South Fork of the Mokelumne river, opposite the San Bruno mine at Mosquito. A small lot of it—five tons—was crushed, yielding 63 ounces. The total yield of the five tons is $1,071—an average of $214 per ton.

THE shaft of the Gwin mine has reached the depth of 1,550 feet. It is stated that work is soon to be resumed on the Banner mine at Mosquito. Prospects are favorahle at the Whisky Slide mine. Hoisting machinery has lately heen put on the mine. Contract has been let to sink the shaft 75 feet deeper.

FRESNO.

CARTWRIGHT MINE.—*Expositor*, July 24: We learn that 30 tons of ore from the Cartwright mine was recently crushed at the Champion mill, and $420 cleaned up as a result. This mine has been prospected to a depth of over 100 feet, and a large ledge, over four feet in width, found as far as prospected. The ore seems to be of a low grade, but there seems to he an ahundance of it. The yield per ton, as indicated hy the clean up, as above stated herein, is less hy far than the actual value of the rock, as the product was ouly the free gold contained in the rock, the sulphurets not being worked. The rock also carries cousiderable silver—some of it more silver than gold, and of this a large percentage is lost in working, as the machinery of the mill is only intended for saving gold. With good machiuery there is no doubt but the ore from this mine would yield, as far as prospected, over $25 per ton, and of this class of ore there are thousands of tons in sight.

INYO.

EMIGRANT.—Coso *News*, July 27: The Emigrant mining company, whose works are situated in Lee district, has placed its stock on sale in the stock boards. It was started at $2.25 and closed at $2.50. As this company is entirely out of debt, and will soon have their mill running at the mines, instead of hauling their ore, as heretofore, nine miles, and paying $14 per ton therefor, we may expect to see Emigrant stock appreciate to quite a respectable figure soon. It is the only company operating in Inyo county that is out of debt; it has good men at its head; and as the ores are high-grade, free-milling ores, there is not a douht that Emigrant will soon take high rank among our best ventures.

LOS ANGELES.

BLACK STAR.—*Republican*, July 23, quotes from the *Gazette:* Two large wagon loads of coal from the Black Star coal mine were brought into town yesterday. A dozen eight or tenmule teams hauling silver rock and coal will make things lively. *Republican*, same date, reports that some old miners are somewhat excited at what they think the excellent prospects of the Silverado mines.

BUENA VISTA.—*Republican*, July 24: It is said that a seven-eighths interest in this mine has been bonded to San Francisco capitalists for $10,000. This amouut has already been expended by these gentlemen in developing the mine.

MONO.

BODIE.—Bodie *Standard*, July 24: All are impressed with the steady and healthy appearance whieh this district is assuming, and there is no longer a doubt of its great mineral wealth. The Bechtel has commenced shipping ore to their new mill, which is rapidly approaching completion, and ere long the shrill whistle will announce her readiness to reduce ore into gold bars. Prospecting is still carried on to a considerable degree and many new claims are heiug located, some of which make a very fair return from assays. When all the mills have started up and are running regularly, this section will make a showing which will surprise many who have heretofore paid but little attention to our district.

LAKE.—Arrangements are being made to put up a 20-stamp mill iu this district.

NEVADA.

DERBEC MINE.—*Tri-Weekly*, July 27: The Superintendent reports that the mine is doing very satisfactorily. A place for a station at the bottom of the shaft is being excavated. The main tunnel is in over 30 feet. In about four weeks tbey will he ready to breast out and hoist the gravel ready for washiug. The arrangements for washing are ahout completed at the surface.

NEW ENGLAND MINE.—The lower level has just heen reached and tho prospects are very good. The ledgo is found to be 16 inches wide and looks well.

PLACER.

CLEAN UP.—*Tri-Weekly*, July 20: The lessees of the Deadwood mine had their second clean-up. The average yield was $57 per tou.

SOUTH YUBA CANAL CO.—Nevada *Transcript*, July 23: The South Yuba Caual company will, within a few days, have its system of telegrapbic and telephonic communication completed, the line reaching to every important station on tbe ditches, in all a distance of a trifle over 184 miles. The whole system is perfectly arranged in detail, and works more successfully than even the most sanguine had anticipated.

ITEMS.—Dutch Flat *Forum*, July 25: The Planet Gravel mining company havo levied an assessment of two cents per share upon the capital stock. Another claim at Michigan Bluff is proving itself to be rich. A prospect was struck in the Swiftsure mine, which yielded $6 to the pan. We are informed that the Florence Gravel mining company at Hunt's hill have discharged all their hands and suspended work. We did not learn the cause of the stoppage.

Placer *Argus*, July 27: The Weske and the Hidden Treasure are paying well. The Swiftsure, the Hazard and others are promising very well indeed. The Van Emon brothers had a satisfactory clean-up at the Big Gun last week. We were shown a $50 nugget that was then taken out.

Placer *Herald*, July 27: The great bonauza of Placer county, known as the "Pike-Bell mine," is still upward in its tendency, turning out the gold in great profusion. The work of pumping the water out of the Lincoln coal mine was commenced last Sunday morning.

PLUMAS.

BELL MINE.—*National*, July 27: The ten-stamp mill is steadily at work on good quartz, and already over $3,000 has heen taken from the hatteries for the month of July. Another cleau-up is yet to he made, which will probably increaso the yield for the month to ahout $4,000. The mine looks promising.

BIG NUGGET.—On Monday, July 22d, Mr. J. M. Jackson picked up a nugget weighing 20 onnces, in his claim, near Long valley.

SHASTA.

COPPER CITY.—Reading *Independent*, July 25: The mill of the Extra mining company is running night and day. They expect to ship two 100 pound hars of silver on the 1st of next month. The town is growing rapidly and overybody thereahouts is juhilant.

SIERRA.

ITEMS.—*Mountain Messenger*, July 27: Work on the Pliocene shaft is being prosecuted vigorously. The Savage company is putting down their shaft rapidly. The North Fork company of Forest City are working about 20 men. The Golden Star is prospering finely, having, beyond question, an excellent gravel miue. The Bald Mountain company have let contracts for $6,000 of mining timbers, and we are informed have let a contract to run several hundred feet of main tunnel. The San Juau company has commeuced a tunnel and are in some 30 or 40 feet.

TRINITY.

RICHER THAN EVER.—*Journal*, July 27: A few weeks ago we mentioned the new discovery hy Trotter, Diener & Co., in their mine at Deadwood, which showed much richer quartz than they had previously found. Since then one arastra has heen run on this rock; 26 tons were crushed in 22 days, aud the result, as we are informed by Mr. M. F. Griffin, is $2,308, or at the rate of nearly $100 to the ton. The lode is now well defined and gives every indication of permauence and continued richness.

GOOD.—Wallace & Hughes, on Trinity, opposite Point Bar, made a $1,000 clean-up last week from a run of onlý five days.

THE Altoona quicksilver mining company will make a good report this season. The retorts were fired up about the first of June and 500 flasks produced in six weeks.

BEAUTIFUL GOLD.—We were last week shown an extra nice lot of gold dust from the claim of Junkans, Schafer & Co. on Oregon gulch. In all there were about $3,000 of the "pumpkin seed" variety, bright and beautiful.

TUOLUMNE.

SOULSBYVILLE.—*Independent*, July 27: The Soulshy mine is in good condition—never better. No. 6 drift going north is producing an abundance of quartz, and the boys say it is very good. Tom West & Co. will start the Independent mine next month by letting a big contract to sink the shaft. Boh Raymond's mine is looking well, with a good suhstantial lode all over her long neglected workings. The Wheal Perran mine is turning out good specimens of rich quartz. The Live Oak is a first-class mine. The rock is full of lead and gold. The ledge is from two to three feet wide.

GROVELAND.—The new pumping machinery on the Mt. Jefferson miue has heen started up aud everything works well so far, and there is a fair prospect of soon having the water out, so that the new proprietors can see what they have in the bottom of the mine.

Nevada.

EUREKA DISTRICT.

THE ALEXANDRIA MINE.—Eureka *Sentinel*, July 28: A number of gentlemen yesterday visited the Alexandria mine, situated on the line of the Eureka tunnel on Prospect mountain. The owners are jubilant over the appearance of the mine, the large cave struck a few days since proving to be to all appearances a vast body of ore. Yesterday about 20 tons were shipped to the Richmond furnaces, assaying $150 per ton.

VARIOUS MINES.—The Republic mine has been leased for a year. The San Jose mine has been yielding some fine ore; a shipment will he made by the lessees this week. The time for the redemption of the Orange tunnel expires to-day. Mr. Pat. Moran will probably fall heir to it, as he has a judgment against it for $2,800. A contract of 50 feet on the main shaft of the Bauner mine was finished yesterday. The shaft is now down ahout 300 feet, being the deepest on Prospect mountain. The face of the drift in the Albion mine is in 14 feet from the shaft. The Ruby hill limestone, in which ore is found, has been entered. The drift is seven feet above the 600 level of the Richmond miue. The hottom of the shaft is in limestone.

MOUNT ROSE DISTRICT.

PARADISE MINES.—*Silver State*, July 27: At a meeting of miuers, held pursuant to call, in tho Paradise mines the following laws were adopted: The name of the district shall be Mount Rose miuing district. The district shall be hounded on the west by the summit of the range west of Paradise valley; on the north and east by Martin creek; on the south by a line running due west from the hot springs situated on the Little Humboldt, ahout six miles from Martin creek. Every claim of 1,500 feet shall have $50 worth of work (or improvements) expended on the same within 90 days from the date of location. That $1 shall he the fee for filing notice of location. That 300 feet from the center of the ledge each way shall be allowed hy the laws of this district. The fees for recording shall he $3 for each notice of location. A. L. Washburn was elected recorder for one year.

NYE.

BELMONT.—*Courier*, July 27: The following is from the superintendent's report: During the past year the main shaft has heen sunk 92 feet and timbered complete, and a crosscut run 60 feet east to the ledge from the shaft on 600-foot station, from which point I drifted south 550 feet upon the vein, exploring aud making the necessary work as profitable as possible. The development made in this drift is a decided improvement over anything found below the old works on the 300-foot level. I conuected the 500 and 600-foot levels by an upraise, made several crosscuts and run a drift 50 feet north ou the 600-foot level, which comprises the principal work done in this part of the mine. There is nearly 200 tons of ore on the dumps and ahout 1,200 tons accessible in the mine. The amount of water is gradually diminishing and is easily handled by the pumps. The main shaft and pumps are in perfect working condition. Wire rope, cages, engines and all other machinery necessary for operatious are in good order.

WHITE PINE DISTRICT.

WHITE PINE.—Eureka *Sentinel*, July 26: A gentleman from Hamilton informed us last evening that the mill at Eberhardt is in full blast, and has an abundance of ore to keep it running for the next six months. He also stated that the Eberhardt & Aurora company, who are runuing a tunnel, which, when completed, will be in a distance of 6,000 feet, and a depth of 1,500 feet, have recently come upon a large body of ore, assays from which yield an average of gold and silver amounting to $60 per ton. This is very encouraging news, as the Eberhardt & Aurora company is, and has heen for a long time, the mainstay of Hamilton. If this news be true, and we have no reason to doubt it, coustant employment will be given to a large number of people. Besides, when it has been demonstrated that there is ore at depth in Treasure hill, there are several wealthy companies in England aud San Francisco who will at once commence mining operations on their old claims, when Hamilton will again come to the front as one of the best mining districts in the State.

Arizona.

SENATOR.—Prescott *Enterprise*, July 24: One hundred and four aud one-half ounces of bullion, the proceeds of 80 tons of ore from the Senator, were received last night by Messrs. Bowers & Richards. The mill is runniug well.

SILVER FLAKE.—Mr. Cherry, who has been examining the Silver Flake and other mines, in the interest of Chicago capitalists, is in town, and though not prepared to report definitely on the recent examination, expresses himself much pleased not only with this section, but with Arizona at large. Says that in his opinion we have richer aud more permanent veins of ore here than are to he found elsewhere in the United States, and he has visited every mineral district of importauce. He meets with a peculiarity in the mineral formations of some portions of Arizona and Sonora that exists only in these sections. The mineral bearing veius do not change with the various formations through which they pass, but preserve their valuable character all through.

PECK.—Late reports from the Peck mill and mine are highly encouraging. The mill has lost uo time lately. Mine is now paying well.

AUBREY.—*Sentinel*, July 27: The new placers, 20 miles above Aubrey, are still attracting much attention. Dry-washing machine up there made $350 in four days.

CHIMNEY PEAK.—The old Chimney Peak placers have heeu galvanized into a new spurt of activity hy the same heavy rains that washed away the railroad track week before last. Tbey are dry diggings, from which immense quantities of gold were worked without water, until that ceased to be profitable. The late rains eompletely soaked the country, filled the tanks, and produced runuing water in several places. This induced working the old ground over again. Some claims are paying $4 to $5 a day to the hand. The diggings are but a few miles from the Colorado river, and will some day be extensively worked by hydraulic process.

The Gila Con. miniug company have ordered an engine, steam pump, a lot of piping, and a large gravel-washiug machine.

Colorado.

SHERMAN MOUNTAIN.—*Miner*, July 20: Since the important discovery made on the Frostburg a few weeks ago considerable interest has been taken in some of the adjacent properties, which are principally old locations, though it is not unlikely that such wholesale denudatiou of old lodes as is now progressing in this vicinity may result in tho discovery of new ones. A healthy impetus has been given to mining ou this mountain, and judging from the incipient devclopments already made, we have reason to hope that labor will not be in vain on Sherman mountain.

EAGLE BIRD.—The lessees on the lower level of this miue are taking out from three to four inches of ore, a late run of which milled 208 ounces for first-class and 110 for secoud-class. The ore is fine-grained, galena carrying gray copper.

PAY ROCK.—The developments on the Pay Rock are progressing with their ordinary uniformity and profitable results. A total nnmber of 68 men are employed who are working under lease with a very few exceptious. Four thousand four hundred pounds of T rail is ordered for the lower level of the mine and will he put in immediately. The company are not doing any work except to make improvements of this kind. Some of the first-class ore mills from 700 to 800 ounces per ton. From four to five tons of a high grade of ore were lying in the ore house when we visited tbe mine in the heginning of the present week.

HYDRAULIC MINING AT NORTH EMPIRE.—The expenses, now that the giaut is started, are comparatively light, but six or seven men being employed. The present supply of water comes from Mill creek, aud the ditch constructed for its transit is four miles in length. The supply from this source is not considerod sufficient and the company are bringing in an extra supply from Mad creek through a ditch two and a half miles in length, which is nearly completed. Two giants will he worked as soon as the water supply is sufficient. A clean-up will probably not he made for a month yet.

LEADVILLE.—The Hall & Cooper lode has

heen worked eight months and the mill returns show a product of $80,000. The Iron is said to be the best paying mine in the camp. It shows from one to 10 feet of ore and in one place the correspondent saw 14 feet that will average 175 ounces. The Gallagher was discovered about 15 months ago. It was worked for a short time, $50,000 was taken out and then the mine was sold to the St. Louis Smelting company for $225,000. Last month the mine produced 600 tons of ore. The same company owns the Pine and Adelaide, lately purchased for $75,000. They anticipate putting up new smelting works. Sander's mine, one-half of which has heen recently sold for $50,000, has an ore vein averaging two feet in thickness, consisting of sand carbonate and galena; the former mills $100, the latter $250. The Little Pittsburgh produces 10 tons per day. In one place the mine shows 14 feet of solid ore, mostly galena. The Yankee claim has yielded $15,000 in five months. Lawson's strike cannot bo developed for lack of water. It is bonded for $80,000. The formation of deposits here is so entirely different from anything before discovered in the State that a description is almost impossible. Even the oldest miners are entirely at a loss, some claiming that the ore lays in contact veins, while others think that the whole country is underlaid with one grand contact, though they are willing to allow that in spots it is barren on account of the strikes that are made in the different localities and the little connection one can possibly make with the other.

Idaho.

ALTURAS.—*Avalanche*, July 27: We are glad to learn by a private note from Judge Anderson, of Rocky Bar, that the mining prospects of Alturas are gradually brightening. There is no section of the country which shows up hetter in rich mines than does Alturas, and the day cannot be far distant that will bring that portion of Idaho to the front as one of the leading mineral-producing regions of the Pacific Coast.

FAIRVIEW.—A rich strike has recently been made in the north extension of the Silver Cord mine, near Fairview, I. T. There is a well defined mineral vein, and the parties interested will go to work next week with every prospect of taking out a large quantity of rich ore.

ATLANTA.—Recently a rich discovery was make by Myers, Steve Hooker and Darbs, in the mountain northwest of Atlanta, and distant about five miles from town, on the tributary of Queen's river, there being three well defined and valuable locations made. Mr. Hooker, one of the locators, was here a few days ago and informed me of the exact location of those mines. The largest of these ledges is about 30 feet in width, with stratas of ore, showing ruby and native silver and assaying as high as 138 ounces of gold to the ton. The location undoubtedly is promising in appearance and will excel the celebrated Atlanta lode. The character of the ore proves without a doubt to be the same as that found in boulders from the John Daily ledge. Superintendent Brown, being interested in the locations, will go to work in company with Mr. Hooker and Darbs to develop this marvelously rich strike and add another link of wealth to Alturas.

VARIOUS MINES.—The Florida Mountain honanza still wears every favorable characteristic, and is steadily looming up. The Black Jack is turning out its usual supply of good ore, and from the crushings at the Ellmore the daily bullion yield of several thousand dollars still continues. The Potosi is turning out an immense quantity of rich rock, and is looking better than ever. The Belle Peck, and other mines in the vicinity of the Poorman, reveal the most favorable prospects, and parties interested in them need have no fears for the future of any mining property in that locality. The Newsome Bros. have met with fair success in the working of their placer claims in the vicinity this season.

Utah.

Salt Lake *Tribune*, July 27: Yesterday fourteen tons of ore from the new Pasco concentrator, located at the Jacobs smelter, Stockton, were sold at $174.20 per ton, assay value, gold and silver. The same ore, before concentration, would not assay more than $15 to the ton, and had in fact heen lying upon the Mono dump for a long time past, literally valueless, heing of too low grade to pay for handling. The process is Pasco's own invention.

New Incorporations.

The following compauies have filed certificates of incorporation in the County Clerk's office at San Francisco:

SHAWMUT G. Q. M. Co.—July 25th. Capital stock, $500,000. Directors—S. O. Putnam, J. S. Bacon, Ira P. Rankin, B. J. Berry and Thomas H. Bacon.

CHAMPION M. Co. — July 25th. Capital stock, $10,000,000. Directors—Henry Epstein, A. P. Williams, R. G. Brown, John Wagner and Robert Harrison.

DOAN G. & S. M. Co.—Capital stock, $150,000. Trustees for the first year, G. W. Hepperly, F. S. Diekerson, Robert Doan, Charles Knust and Mark Parish.

THE Southern Pacific railroad company have hored an artesian well uear Tipton, Tulare county, with flattering success. The well is 310 feet deep and yields per day 86,000 gallons of water, containing hut six grains of solid mattor to the gallon.

News in Brief.

PERSIA is to have her first railroad.

PRESCOTT, A. T., has a new theater.

J. A. PHILLIPS has returned from a trip to Washingtou Territory.

ALL the powers except the Porte have ratified the Treaty of Berlin.

UNION COLLEGE has given Edisou the degree of Doctor of Philosophy.

THE Russians estimate their total war expenditure at 988,000,000 roubles.

HON. HORACE DAVIS and Milton S. Latham have returned from tho East.

PROPOSALS will bo made in September to make Sorvia a kingdom.

AT Santa Monica, the 21st of July, a shark weighing 125 pounds was caught.

TWO poets, Tenuyson and Tupper, have grown rich on the England of the present.

ON the 27th of July a hark from Matanza arrived in Florida with yellow fever aboard.

THE Whitworth 38-ton gun, recently experimented upon at Woolwich, proves to be a failure.

AT Lincoln, Placer county, Cal., 300 acres of wheat and stubble were burnt over on the 22d of July.

THE damage done in Tucson, A. T., by the recent flood is estimated at $40,000 and upwards.

YELLOW fevor continues at New Orleans. Total number of cases, 50; deaths, more thau half that.

A BALE of cotton from Memphis was awarded the first premium at the Paris Exposition Saturday.

THREE Sundays in succession, ending with June 30th, London was visited by terrific thunderstorms.

ON July 26th Gen. Garfield, while bathing in the surf at Atlantic city, N. J., was taken with vertigo.

EFFORTS are being made for the establishment of a line of steamers between Cuba and the ports of the Republic of Honduras.

EXPLORER STANLEY is said to have accepted a propositiou, made by the King of Belgium, to defray the expenses of another trip across Africa.

GENERAL SHERIDAN expresses the opinion that a permanent military post will he located at some point between the Spearfish and Rapid Creek valleys.

FOR the first time since 1852 a formidable plague of grasshoppers threatens destruction and desolation to the crops of the husbaudmen in Salvador.

THE first embassy that has ever been sent hy the Republic of Mexico to the sister Republics of South America has passed through Panama on its way south.

SENOR CASSANUEVA, who vouched for the respectability and scientific attainments of M. Paraf, has been removed from his post of Consul-General of Chile in California.

ON the 26th of July 22 tons of fine silver bars, valued at $750,000, were shipped from the assay office in New York to the Philadelphia Mint for coinage into standard silver dollars.

REPORTS coming in from Northern Iowa and Southern Minnesota state that the crops are badly damaged in those sections. Wheat in some counties will not yield over seven bushels to the acre.

GRASSHOPPERS are desolating many districts of Honduras. Crops disappear before them in a day, and the sparsely populated localities are entirely at their mercy. The Government calls upon the people to unite in some systematic way to drive off the destroyers.

THE Argentine explorer, Don Frau. Moreno, claims to have discovered the Patagonian volcano, seen by the U. S. steamer *Omaha*, and named after that vessel, nine months previous to its discovery by that vessel. He saw it in eruption March 3d. It is the most southerly volcano yet discovered.

ISAAC HOWELL, SR., died at his residence in San Luis Ohispo on the 4th of June, aged 80 years. Mr. Howell removed from New York State to California with his family in 1846. In 1848 he settled in Napa county, where he lived 23 years, having moved to San Luis Ohispo with his wife about seven years ago.

ON July 22d a cloudhurst occurred about 40 miles north of Yankton, Dakota, hy which a large portion of the country was suhmerged and seven persons drowned. The west branch of Vermillion river, ordinarily ahout two rods wido, was filled to a width of over a mile and a depth of from ten to three feet. Much destruction of property is reported.

LIEUTENANTS RUCKER AND HENELEY of the Sixth cavalry, highly esteemed for their successful efforts to rid Arizoua of Apaches, were drowned in White river, at Camp Supply, about the 12th. The storm had swollen the river. Lieut. Heneley in crossing was unhorsed and swept down the stream, receiving a death stroke from a stump or log. Rucker went to his rescue hut was overcome hy the boiling current.

ON July 28th Ex-Governor George L. Curry, of Oregon, died, after a long and painful illness. The deceased came to Oregon in 1846, and soon after his arrival there assumed editorial charge of the *Oregon Spectator*, at Oregou City, the first newspaper published in the country. He was, about 1854, appointed Governor of the Territory hy Pierce, and held that position until the organizatiou of the State Government in 1859. His life has heen active in both politics and private husiness; yet he leaves a spotless and honored name—a great thing uow-a-days.

THE Sultan has ratified the treaty of Berlin.

RUSSIAN and Roumanian troops are returning home.

IN the whole territory of Montana there are 24,590 Indians and 2,094 soldiers.

COUNT ANDRASSY'S only daughter is to marry Prince Alfred of Montenneva.

NUBAR PASHA has been summoned from Paris hy the Khedive to aid in reform in Egypt.

ON July 30th a construction train with four flat cars was wrecked near Vallejo by a displaced rail. Nobody hurt.

A SHOCK of earthquake was experienced on July 26th at Los Angeles, San Bernardino, Riverside and other points in Southern California.

A FAMILY in New Orleans of four persons were poisoned by using oxalic acid for sugar in cooking. One died and the rest may probably recover.

SOME extensive placer mines about 240 miles up the river from Yuma lately discovered are worked by dry washing and yield from $4 to $20 per day to the man.

FOURTEEN children and three teachers were drowned by the capsizing of a boat July 26th on the river Blackwater, near the town of Ballieborough, Ireland.

KING ALFONSO has not recovered from the deep melancholy with which he has been afflicted since the death of Queen Mercedes. It is feared he contemplates abdicating and retiring to a monastery for the remainder of his life.

A CHILD was lost on the desert near Moore's station, on the railroad, about the 16th. It wandered about in the hot sun without food or water for four days, when it was tracked and found by its father. When found it was crazy, but soon recovered.

ON the 21st of July a young lady of Sonora picked up a giant powder cap with a hair-pin. The cap exploded. The thumh and fore-finger of her left hand had to be amputated. The third finger is hadly lacerated and a piece of the cap struck her forehead.

THE steamer *City of Tokio* arrived in San Francisco nine days behind time, having heen under sail 13 days during the trip—her crankpin broken. She made the qnickest time on record between Hongkong and Yokohama—4 days, 20 hours, 40 min. The Chinese Embassy came on the *Tokio*. It cousists of 45 persons. Sit Ming Cook is the Chinese Consul for San Fraucisco. He is a very bright and intelligent young man. He has received a thorough English education at New Bedford, Mass.

HIS excellency, the Embassador from China, is upwards of 60 years old, with scanty whiskers about the mouth and chin. His features are regular, his countenance intelligent and pleasing. In fact, all of the members of the suite are well-bred, polite, aud have bright, intelligent faces. He is Lieutenant-Governor of the Imperial family, which, in a measure, is under his jurisdiction. He was Imperial Commissioner to the United States in 1875, and has also heen a Commissioner to England and Spaiu. His own suite consists of 22 persons. His mission to this country is to establish the consulates and to transact some lesser diplomatic business. He will present his credentials at Washington, have the Cousuls recognized, and then go to Spain and Peru to establish consulates there.

Caribou Mines.

EDITORS PRESS:—Please give me an opportunity to correct the statement of my heing employed in the examiuation of the Caribou mines, as I have not heen engaged in that work, notwithstanding much talking, telegraphing aud printiug towards that end, at Caribou, Victoria and San Francisco.

I have, however, just returned from British Columbia, where I have heen engaged for several weeks assaying rock from many sections and examining quartz veins on Vancouver island; and as it was quite novel in incidents and may be interesting to your numerous prospectors I will, with your permission, give them a description in your next issue of my 160 miles' walk through immense forests and thick undergrowth, and some general ideas of the rocks aud minerals of that portion of the island.

J. S. PHILLIPS.

San Francisco, August 1st, 1878.

DRY PLACERS.—Placer diggings are reported to have been found near the Colorado river, in Arizona, and about 240 miles above Fort Yuma. They are worked, as all similar deposits in that region are obliged to he, hy dry washing, and are said to yield fair wages. This is a difficult section of country to reach and a hard one to live in, and unless these diggings should prove to be much more extensive than any others ever found in that part of Arizona, this discovery ought not to create much excitement among our mining population. The La Paz placers, situated ahout 100 miles above Yuma, which caused sueh a stampede across the deserts in the summer of '62, turned out to he of hut limited extent, though they made a great noise at th time.

THE Elephant ore-stamp is a device for crushing ore recently brought out from England, now being introdueed ou this coast. One of these machines may he seen at work at the corner of Main and Harrison streets every day from two to four o'clock, and is well worth examination by the mining community. We will have a detailed description of this new device in our next week's issue.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington, D. C.

RAILWAY CAR TRUCKS.—Wm. R. Hamilton and G. Canning Smith, Mendocino, Cal.

WINDOW-SCREENS.—John Brizer, Alvarado, Cal.

HORSESHOES.—Hiram M. Clemons, Gold Hill, Nev.

NON-CONDUCTING COMPOUNDS.—Geo. R. Evans, San Francisco, Cal.

SAFETY HOOKS FOR HARNESS SADDLES.—Wm. H. Henderson, San Jose, Cal.

APPARATUS FOR TRANSMITTING POWER AND MOTION.—Carl L. Henrich, San Francisco, Cal.

TURN-TABLE FOR SEWING MACHINES.—Eugene Moreau, San Francisco, Cal.

VALVES FOR WATER CLOSETS.—Wm. Smith, San Francisco, Cal.

SHIELDS FOR THE TOPS OF CRUCIBLES OR MELTING POTS.—Jno Feix, San Francisco, Cal.

REISSUES.

CLACK-VALVES FOR PUMPS.—Wm. C. D. Body, Virginia City, Nev.

TRADEMARKS.

COD FISH.—Lynde & Hough, San Francisco, Cal.

CHEMICAL COMPOUND FOR THE COMPLEXION.—Chas. R. Burrage, San Francisco, Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

VALVE.—Thos. Hennessey and M. H. Dorgan, S. F. The valve is of that class used for regulating the supply of water or other liquids to hasins, tanks, etc. The improvement consists in so constructing a vertically moving valve as to close automatically by the action of the water. The valve has a long stem, extending upward into a recess in a spindle projecting through the top of the chamber, so that when it is desired to allow the water to flow the spindle is forced down by a screw lever or other means, thus hurling the valve clear of its seat hy means of the stem. By raising the spindlo and relieving the downward pressure, the water in the supply tube, by its upward pressure, forces the floating valve into its seat and shuts off the water. This form of valve will be specially useful in cold climates, where water in the house pipes is apt to freeze at night. In such places it is customary to disconnect the house pipes from the mains and draw off the water from the house pipes, by opening a faucet in the lower part of main supply pipe. Thus all the faucets in the house have to he opeued to admit air above, so the water can flow out. With the improved valve, as soon as the water below is turned off and pressure released, the valve drops from its seat and all the water in the house pipes runs off. When the water is again turned on the valve is forced to its seat, thus acting automatically in each instance.

VINEYARD PLOW.—Milton Ross, San Jose. The inveution is in connection with that class of vineyard plows in which the rear end of the plow heam is adjustable, so as to throw the forward end of the heam either to or from the land side for the purpose of clearing the douhletrees from the vines or other growing stalks, near which it is desired to plow, and it is especially applicable to a device previously patented hy the samo inventor. It consists of a novel application of adjustable handles, swiveled to a movahle har in combination with an adjustable heam mounted on a crank pin, or post, and iu comhiuation with a draft har. It also consists of a method of locking and holding the various parts in proper position for ordinary or vineyard plowing, aud whenever it is desired to plow close to the growing vines, trees or plants, etc. By using the peculiar locking devices the plow may he used for ordinary work also. The workman is always in a position to guide the plow while he can also walk clear of the vines. The handles can be raised or lowered to suit varying hights of men or to pass under limhs.

THE attention of our readers is directed to the advertisement of Messrs. Anderson & Randolph, jewelers, in the clock tower huilding, formerly occupied by Tucker, the pioneer jeweler of this city, No. 101 Montgomery, corner of Sutter. These gentlemen have, in addition to their magnificent stock of watches, diamonds, jewelry, etc., a fine assortment of Vienna goods, art novelties, bronzes, statuary, clocks, etc. A specialty is made of fine quartz jewelry of their own manufacture in unique patterns and elegant finish. No house ou the Pacific coast can show so large and varied a stock of choice goods in this line. A call at their store will not be amiss, especially hy those not already acquainted with the firm and their manner of doiug business.

A COMMERCIAL treaty betweeu Frauce and America is under consideration.

Men and Machines.

Several notable advances made of late in the design and manufacture of agricultural machines, have awakened anew the discussion of the effect to be expected from the growth of labor-saving machinery. The question is an old one, and we do not see that anything has occurred which should change the old verdict that, though the introduction of a new labor-saving implement may, for a time, work to the disadvantage of certain bodies of citizens, there soon follows an adjustment of affairs to meet the innovation, and the stream of progress and prosperity pours along just as deep and wide as ever. Just now there is the louder outcry because agriculture seems to be enjoying unusual favors from the inventor. People generally have come to falsely look upon agriculture as a dull, plodding and intensely conservative industry, and they are the more surprised and alarmed when their eyes are pried open by the lovers of some new machine and they behold the lifeless occupation alert and moving forward, rapidly forward. The people affect to be alarmed because the self-hiuder has excited the threats of a few men whom their owu State has justly pronounced outlaws. They peer into the future through clouded eyebrows, because the header and thresher have been successfnlly combined and the farmer's power over his field has been increased many fold. We do not see why these improvements should excite greater alarm than other just as great improvements which have aided the manufacturer, the miner and other producers iu their work. Is the self-binder a greater advance from the sickle than the power loom is over the cloth-making apparatus of our grandfathers? Is the combined header and thresher more effective iu labor-saving over the old swinging cradle than the many-stamp quartz mill is over the primitive arastra? It is common to cite the indignant protests of the London pressmen over the introduction of the power press as an example of mistaken zeal, because the increased demand for printed matter afterward kept them all fully employed, even with the best machinery which could be devised to aid them. Nor has the progress ever halted for an instant. The people now demand such a number of papers upon their breakfast tables that they must be snpplied by a press which helps itself from a continuous roll of paper, makes its impressions, cuts and folds its sheets ready for the carrier—turning out, without humau aid, its thousands of impressions, where its forerunner issued hundreds, with the aid of many hands.

It is time that the progress of labor-saving machiues in agriculture may not find its beneficial effects wrought out in just the same way that they have heen in the progress of other industries, but this gives no reason to distrust their ultimate coming. There is every evidence to argue by analogy that the results will be ultimately good. There is no welfare of the race which demande that one industry should be speeded forward and another held stationary or restricted to sluggish growth. This theory has prevailed to a certain extent, it is true, and it has been held by other people than politicians that farmers should occupy the back seats in the car of progress, but such an idea is false to every sound theory of political and industrial advancement.

It is a plain fact that without labor-saving machinery the agriculture of all the newer States would remain undeveloped to this day, and the rapid increase of people in this country would be swarming, shirtless and supperless upon the Atlantic seaboard. Without labor-saving agricultural machinery California could never have exported a pound of grain; her few farmers would have done well could they have fed themselves and the miners. With such a history of results attending the progress of agricultural machinery, why should we distrust its further advancement? With leagues of uncultivated land in our own State, why should we malign the very agency which is to bring it into profitable production? With the great unoccupied northwest, which can yet be carved up into prosperous States, with climate and fertility which the world cannot surpass, why ehould agriculture be called upon to halt in her advancement when she alone holds the key which can unlock these treasures?

It is true, perhaps, that the growing application of machiuery to agriculture will work hardship to some of our laboring population, as successive improvements are first reached. This is to be regretted, but it seems unavoidable. This seems to be the price at which the nation buys every step in industrial progress, but as this hardship has always heretofore been followed by compensations, why should it now come without attendant rewards? It is not given to the most farsighted to penetrate the future, except as the past indicates its probabilities. This method of forecasting the future certainly gives assurance, not ground for alarm, in the special line which we are considering.

We cannot see how help will come to the thousands whose work the new machines are doing. Agriculture has so long heen looked upon as the kind mother who shall feed and clothe all the broken and distressed from all other occupations, that it is little wonder that her reduced dependence upon manual labor is viewed with anxiety. It is easy to say that, as an abstract proposition, it is plain that men must enter agriculture more as masters than as journeymen; that those who are thrown out by the progress of agricultural machinery must go upon the new fields at a distance and huild themselves up as those bave done who are now profiting by the use of the machines that laid tbe fouudations of their prosperity. How shall they who are now tramping from kitchen to kitchen around the State be embued with the disposition to move into the open lands aud to do there what tbey fail to do here, uamely, to labor. And how are they who have the disposition, but cannot find work, to get start enough to get to promising fields and obtain food, seed and implements with which to maintain themselves and put in their crops. This we acknowledge we do not know. To restore the qualities of manhood in those who are heartless, homeless, ambitionless, is perhaps a problem in mental, moral and social science which the doctors in those philosophies can solve; we cannot. To provide material for those who have the will to use it is a question of finance and political economy which is beyond our pocket and our brain. And yet while stumbling on these blocks hewn from the impossible, we are strong in the belief that other causes than the progress of labor-saving machinery are to blame for much of the evil and lack which are iu these men's minds and stomachs. So far as mechanical progress is concerned we believe it will be, as it has heen, one of the chief agencies in the world's advanccment. None can stop its course. Those are safe who can climh into its car; those in danger who sport beneath its wheels.

Names of Mines.

Why the Boys are so Peculiar in Their Selections.

Names of mines, like one's emotions when eating Limburger cheese for the first time, are peculiar.

The locator of Dry Hash prohably showed his preference for a dish which is a prominent feature of boarding houses, and has a large circle of acquaiutauces. Mooubeam, indeed, is more poetic but not so euphonious, nor so suggestive of Utah as Boss Bedhug. Little Bilk leaves one to infer that there is a Big Bilk; in fact, on consideration, we'll concede that there are a great many of them. Mollie Darling shows that, although she is getting to be quite an old maid, she still has admirers. The Fraud is an exhibition of human nature; the locator wanted to prick the pride of the vein and spur it to belie its name.

On inquiring of one miner why he had named his claim "I Know All" he explaiued:

"When I left the East, left my girl there, and—and some trouble I had with another lady. When I got out here, wrote to my girl that I was doing bully. That wasn't so, but you know how a fellow will write. Wrote that I expected to return soon and cage her in a palace. She answered: "I know all. Yours no more, Jane."

Asking another why he chose to name his mine the Terror, he replied:

"For a lady."

"How? Didn't know that was a female name."

"Well, you eee, that's my wife; she's a holy terror. Left her in Gold Hill."

The owner of Damn the Luck said;

"Two of us started out prospectiu', and had two mules. On the mornin' after the first night we had one—other choked hisself to death with the rope. Next day t'other mule went over a precipice—we had noue."

"Lost your tools?"

"No," sadly and respectfully.

"Grub?"

"Worse."

"What?"

"The hig canteen, qnarter full of whiskey, went over with that mule. Damn the Luck was located soon after that."

Tom Pike, being questioned as to his naming a location Joab Johnson, said:

"That—that—was my name in the States."

"I asked the proprietor of the Last Chance if he really considered that his Last Chance for a fortune; if he failed would he try it again?"

"No, sir; no, sir; will go to robbin' the stages!"

Ever of Thee seemed to whisper of an absent object of love. Said I to the owner:

"That name was coined by your heart; she comes to you in sweet dreams?"

"Yes."

"And by day your thoughts turn fondly to her?"

"Yes."

"Ah, fond hearts sundered by cruel circumstances. Are you long parted?"

"Very."

"Her name, good man. Perchance I may meet her in my travels and tell her of thee."

"Nancy."

To the man who was showing me his two claims, I remarked:

"From the name, the Treasury, you must have high bopes of this?"

"That isn't why I named it that."

"Why, then?"

"There's nuthin' in it."

"And this second one, Hector; you admired the valiant Trojan?"

"Named for my dog, Hector. He's dead. Buried over thar; come and see his grave."

"No, I was just passing."

Saying to a miner, one of a family: "What fancy led you to name this claim Tim Finnegan?"

He replied:

"Well, stranger, it was at Prescott, an' me an' Tucson Jake was a playing a game of kersock, jess fur the drinks, you know, when in comes one of them crazy, hlood-thirsty hell-hounds that turn loose in mining camps sometimes, ripped out his six-shooter, shoote the barkeeper dead, then, turnin' on me and Tucson Jake, said:

"'Now, either of you move an inch an' I'll blow the top of your d——d heads off!'

"We knew he'd do it. Thar was the harkeeper dead, and thar was the' pistol pointing right at us. It was fearful, we dasn't take a full hreath. Jake's feelings worked on him so powerful that he could not keep still; he hitched around a little. Quick as lightning a bullet laid him at my feet! Now the pistol was turned towards me, with the muzzle within three feet of my face, an' the eyes of the scoundrel fairly hlazed as he said:

"'Move, move, damn you, jes' the hundredth part of an inch!'

"It was the most horrible time of my life. The sweat stood on my face like cobblestones. I knowed he'd kill me if I moved an inch, an' it seemed all the time as if I was going to move in spite of myself. I even wished he'd shoot me an' have it over with. Jus' then a pistol shot flashed behind the wild beast an' he fell dead in his boots.

"Tim Finnegan had got too much whiskey early in the evening, an' stretched out on come barrels in the corncr an' went to sleep. The shots that had killed the barkeeper and Jake waked him. An' unbeknownst to me an' the murderer, easily and gradually got out his pistol and sent the bloodhound to kingdom come."

"You fled from the scene of horror?"

"I hugged and kissed Tim."

"What is the name of this prospect in front of us?"

"Tim Finnegan, No. 2."

"The one to the right?"

"Tim Finnegan, No. 3."

"Aud this on the left?"

"Tim Finnegan, No. 4."

"How many locations have you ou this hill?"

"Sixteen."

"The name of the last one?"

"Tim Finnegan, No. 19."

"How is it that you have No. 19 and only 16 locations?"

"My boy an' my horse an' my dog is Tim Finnegan, Nos. 16, 17 an' 18."

"You havn't named your wife that?"

"No, hut if I die before her an' Tim—he's a hachelor—I want her to be Mrs. Tim Finnegau."
—*Salt Lake Tribune.*

The Lake Dwellers.

One thing is abundantly clear, that the tribes who huilt and inhabited these lake dwellinge were not the rude savages they are sometimes said to he. The earliest settlers appear to have heen not ouly fishermen and hunters, they were also shepherds and agriculturists. No doubt the idea of such buildings arose out of the necessity of securing the lives and properties of the people from the attacks of enemies. The large number of skeletons of fish, aud especially the skulls of very large pike, which have been found buried among the piles, prove that they were expert and skilled fishermen; the bones, which lie about in the lake dwellings iu astonishing numbers, of stags, roes, wild boars, beavers, otters, squirrels and other animals, are an evidence of the abundance of game, and of the ability of the settlers to bring down even the higher description of wild animals. They, however, did not depend on the precarious and uncertain produce of hunting and of fishing. Many of the animals which are still the companions of man, such as cows, sheep, goats and pigs, had already been domesticated by them; aud the keeping of cattle necessitates an amount of forethought and of provident care for the future which raises those who are capable of it above the level of the savage. A great variety of seeds and plants were also cultivated for their own use and for the use of their cattle. They possessed and cultivated flax of excellent quality, and the state of the industrial arts among them showed considerable proficiency and skill, and proves that even their society was so far advanced and settled as to demand a division of labor and fixed lines of occupation. They were in the habit of housing their cattle and swine in the winter time, of laying up stores of acorns, beechnuts and fodder for their use.

Virchow bas declared that as regards man himeelf, the skulls of the lake dwellers might pass muster with the average skulls of the present generation. A question full of interest to science is, Who are these ancient people? Of what race were they? Were they one people through the successive ages of stone, bronze and of iron, or was each age heralded hy a new invasion? The evidence goes to prove that it was one race who successively advanced from one stage of civilizatiou to another, who, when by accident their houses were burnt down, again rebuilt them on a higher level. Were they Celtic or were they of the nou-Aryan race, said to be represented by the small, dark Basques, the swarthy Iberian? Other questions also arise which cannot yet receive a positive answer. By what meaus were the weapons and implements of bronze suhstituted for those of stone, and how did iron supersede the inferior by the slow results of trade, or were they discovered by the lake dwellers themselves?—*Lond. Spec.*

Metalliferous Mines of Great Britian.

The annual reports of the mine inspectors recently published contains a summary by which it appears that in the aggregate in the year 1877, 57,395 persons were employed in and about the mines of Great Britian and Ireland under the Metalliferous Mines Regulation Acts, exclusive of those employed at the mines, which are classed under the Coal Mines Regulation Act. Of the total number of persons employed in Great Britian 32,954 were underground, and 22,396 above ground, and in Ireland 1,141 under ground, and 904 above ground. A summary of the mining produce for 1877, given either in districts or counties, shows that in the aggregate the following quantities of minerale were produced:—Arsenic (ohtained at the mines), 4,110 statute tons; arscnical pyrites, 5,341; barytes, 19,161; hauxite, 2,763; brick earth, 2,411; building stone, 331,101; calc spar, 5,353; cement stoue, 2,304; chert, 3,290; copper ore, 2,217; copper precipitate, 628; dross spar, 142; fireclay and brick earth, 756; flagstone (dressed), 1,830; undressed, 250-2,080; fluor spar, 77; gannister, 439; gold 61 lbs. 11 oz.; gold ore, 1 cwt. 3 qrs.; gold sulphurets, 2 tons 19 cwt.; gypsum, 73,908 statute tons; iron ore, 2,815,-848; iron pyrites, 17,794; jet, unknown; lead ore (dressed), 76,471; lead ore (undressed), 3,-938; limestone, 528,010; manganese, 3,038; ochre and umber, 2,867; phosphate of lime, 6; potters' clay and other clays, 41,819; Purheck stone for paving, kerbs, etc., 13,228; rock salt (exclusive of the white ealt made from brine), 207,942; silver ore, 142; slate and slabs (dressed), 172,130; slate (undressed), 80; steatite, 68; tamping stone, 100; tin ore, dressed (black tin), 12,665; tin ore, partially dressed (white), estimated to contain 34 tons of black tin, 1,022; tin ore undressed (tin stuff), estimated to contain 595 tons of black tin, 11,511; uranium ore, 2 cwt.; whinstone, 18,308 statute tons; wolfram, 15; zinc ore, 24,227. In the year 1877, at the mines classed under the Metalliferous Mines Regulation Act in Great Britain and Ireland, the fatal accidents amounted to 87, and the deaths (some of the accidente causing more than one death) to 97. Of these, 86 deaths occurred underground and 11 above ground. Thue, in the year 1877, there was one fatal accident among every 651 persons employed in and about the mines, and one death among every 587 persons so employed.

The Murchie Mine.

We yesterday, says the Grass Valley *Union*, paid a flying visit to the Murchie mine, but were there long enough to see that things presented a very healthy aspect. This mine is situated on Deer creek, about a mile above Nevada, and is worked at good profit. It is one of the oldest mines at present working about Nevada, having been in operation some 15 years. The shaft is down 400 feet, with a good ledge. The rock is raised by steam hoisting works, situated on the hill-side, some distance above the mill, and is from there run on a tram-way down to the mill. This tramway has a double track, and is so arranged that the full car going down to the mill hauls the empty one up. The mill is at present a small one, having in it only ten stamps, hut men are at work putting in eight additional stamps, that being all there is room for in the mill building. We were informed by Mr. Perkins, the Superintendent, that the company also intend to put in a number of additional pans, conceutrators, etc., pieces of apparatus which are somewhat lacking at present. The mill was originally run by a large water wheel, and its present location so far below the hoisting works was determined by that fact, it being necessary to put it down there in order to get enough fall; but some time ago steam power was suhstituted, on account of the water supply being uucertain at times. There is wood enough on the company's grounds adjoining the mill to last many years. The rock at present coming from the shaft looks very fiue.

A Heavenly Phenomenon.—A very curious and interesting phenomenon was observed on the night of the 11th instant, at McKeesport, in the system of the planet of Jupiter. It was first seen at about 10 o'clock, and appeared like a notch or indeutation on the eastern edge of the planet. Five minutes past 10 o'clock, and in the eastern margin of the disc of Jupiter was seen a very dark round spot, just above the northern belt. It soon moved rapidly westward, just touching the belt and parallel with Jupiter's equator, and passed off the face of the planet at 1:24 o'clock A. M. of the 12th. Its appearance while passing across the disc of Jupiter was that of a perfect sphere or globe much larger than any of Jupiter's satellites. It appeared to etand out in space between the planet and the observer, was well and shapely defined, and most intensely hlack. It reflected no light, and was not seen either hefore or after its passage across the planet. Now, what was it? It was not a spot on the globe of Jupiter, for it passed over its disc from first internal contact to last external contact of margins in three hours and 19 minutes, too little time for the passage of a spot. It was not a satellite, nor the shadow of one, because all the four satellites were in full view all the time. One of them went into transit at 11:15 o'clock, and presented no unusual appearance; its shadow followed the dark object westward. At last accounts only two observers, and both of these at the same place, have been heard from.—*Pittsburgh Chronicle.*

New Mexican Mines.

A correspondent of the Georgetown (New Mexico) *Herald*, writing of that camp says:

We have in our mining camp two things particular to complain of. The first is milling capacity to reduce our ores in anything like decent time after they are extracted from the mine. 'Tis true we have two quartz mills within three miles of here, but one of them runs exclusively on their own ore, and the other nearly half the time in the same way, and the capacity of the last is only about three tons per day, which gives very little time for working custom ore. Now, our camp certainly turns out not less than ten tons ore per day, and would with a very slight increase of working force more than double this number, if we shall include low grade ore, which will run from 30 to 50 ounces per ton. But of the amount actually taken out at present, say that each mill has a capacity of 3½ tons, this leaves three tons surplus ore which is being piled up on the dumps waiting to be worked. Formerly a great deal of ore went to Silver City to be worked—of late none has been taken there and the consequence is that it is fast accumulating for want of mill capacity. This is certainly a draw-back to the prosperity of our camp in more ways than one. In the first place the poor lessor who has been working hard for a month or two or three months, and has in the meantime gone in debt, strained his credit and has been lucky enough to take out a few tons of ore, has to wait two or three months to have it reduced. This fact staring in the face deters poor men from taking leases and causes those who have the means of assisting them to refuse to do so, knowing as they positively do that they will have to wait from four to six months for their money. On the other hand if we had the necessary milling capacity there would be no necessity for delay longer than 30 days in any instance, in the way of payment. When parties might require assistance the merchants would therefore be able to extend short credit to miners in the way of furnishing provisions, powder, fuse, steel, etc., knowing that they would not have to wait always for their pay. It is not the fear of losing that causes our merchants to refuse credit to the miner, but it is the actual certainty of having to wait several months for their pay. The consequence is, that if a man has not a few hundred dollars in his pocket, be cannot take a lease, and be is compelled to work for wages if he is lucky enough to get work, or travel to some other camp.

That we have a good and paying mining camp, no one will pretend to deny, the fact that there has never been a dollar brought into it for mining purposes, and that hundreds of thousands have been taken out of it, proves this beyond a doubt; and that under a thousand difficulties, ore that now pays 200 ounces per ton formerly brought the miner, we well remember, out in debt. When John Wood, of your city, and S. S. Brannin, former owners of the "Sunshine," took 40 tons of ore to the mill that would now pay them nearly 200 ounces per ton, and brought them out $40 in debt. This was at the time that Burlingame had charge of the Tennessee mill.

This difficulty of having ore worked brings about another cause of complaint, and that is this store order system that our miners have been compelled to resort to, to pay their laborers. In a camp like this which employs nearly 200 men, there should be paid out some $500 or $600 daily in cash, but on account of this order system we hardly ever see a dollar in money.

Now our only remedy for those evils is more mill capacity. A mill right here in Georgetown is what we want most of all, with capacity of eight or ten tons. It is true water is not overly plenty, but a sufficient supply could easily be had by means of tanks and dams, and I have no doubt that by sinking 50 feet in the bottom of the gulch permanent water could be had sufficient for a ten-stamp mill.

To show something of the importance of our camp in a mining point of view, we will state that there is now being taken out not less than ten tons of ore daily, which is a low average estimate. This ore will average $125 per ton, making a total annual product in round numbers of 3,000 tons; at $125 makes the annual product of $375,000; and with capital and good management the product would double this amount very readily.

Messrs. Kennedy and Harper are to bedrock with their shaft and have made connection with the old drift, and will shortly be taking out plenty of good metal.

Lynch & Farrell are through the slate and into the talc, which shows that they are near the bedrock, so they will soon strike the ore that they could not get at on account of foul air.

Sullivan brothers are now working in the deep shaft sunk by Rusty and Moulton, and they are taking out good ore and considerable of it. They intend to force air into their shaft by means of a fan.

John and Murdoch McGregor and McLaughlin are taking out good ore in large quantities on their lease on the "McGregor."

Chick Hughes & Co. are still taking it out fast and to all appearances of good quality. If it lasts over two or three weeks I suppose they will turn over to some one else, as they say they will have enough to do them by that time.

Wm. H. Wray is taking about four tons a week out of the "Uncle Sam," good ore, working two hammers and has about 20 tons on the dump. He thinks it will average 100 ounces.

Useful Information.

Hints to the Users of Belting.

The following hints on the use of belting are drawn from recent writers on the subject. Many of the hints will be found familiar to experienced shop men and will serve as verification of their practice:

Belts stuffed with tanners' dubbin on the flesh side will become as smooth as the hair side, and will outlast six belts which are run on the hair side exclusively.

Three times the adhesiveness is gained by softness and pliableness of belting leathers over those which are dry and husky.

Long belts are preferred to short ones, but care must be taken that the length be not too great.

Horizontal, inclined, and long belts give a much better effect than vertical and short ones, and those that have the driving side below than otherwise.

Belts of coarse, loose leather will do better service in dry, warm places; for wet or moist situations the finest and firmest leather should be used.

Experience says the hair side of a belt put next to the pulley will drive 34% more than the flesh side.

The strongest part of belt leather is near the flesh side, about one-third the way through from that side.

Leather belts must be well protected against water, and even moisture.

Short belts require to be tighter than long ones. A long belt, working horizontally, increases the tension by its own weight, acting in the curve formed between the pulleys.

Sufficient care is seldom taken to let belts run free and easy, and it has been one of the greatest errors, more or less prevalent in all cotton or woolen mills, to run the belts so tense as greatly to injure the belts and rapidly increase the wear of the bearings.

In many instances the tearing out of lace holes is often unjustly attributed to poor belting, when, in reality, the fault lies in having a belt too short, and trying to force it together by lacing, and the more the leather has been stretched while being manufactured, the more liable it is to be complained of.

To obtain the greatest amount of power from belts, the pulleys should be covered with leather; this will allow the belts to run very slack, and give 25% more durability.

A careful attendant will make a belt last five years, which, through neglect, might not last one.

It has been found in practice that belts must not run faster than 30 feet per second, nor have a tension of above 300 pounds per square inch of section.

The friction of a belt is double on wood what it is on cast-iron.

Long belts are less liable to slip than short ones.

The softer woods are better for pulleys than the harder kinds, but pear-wood and nut-tree are best for cord-wheels. Grease must not be put on wooden wheels on which belts run.

Tightness by tightening pulleys must be applied to the slack side of belts.

The belts should be cut from the center of the skin.

Thickness of belts does not always give strength.

If too great a distance is attempted, the weight of the belt will produce a very heavy sag, drawing so hard on the shaft as to produce great friction in the bearings, while at the same time the belt will have an unsteady, flapping motion, which will destroy both the belt and the machinery.

The connected shafts should never, if possible, be placed one directly over the other, as in such case the belt must be kept very tight to do the work.

It is also desirable to locate the shafting and machinery so that belts shall run off from each other in opposite directions, as this arrangement will relieve the bearings from the friction that would result where the belts all pull one way on the shaft.

If possible the machinery should be so planned that the direction of the belt motion shall be from the top of the driving to the top of the driven pulley.

The diameter of the pulleys should be as large as can be admitted, provided they will not produce a speed of more than 3,000 feet of belt motion per minute.

In punching a belt for lacing, it is desirable to use an oval punch, the longer diameter of the punch being parallel with the belt, so as to cut out as little of the effective section of the leather as possible.

Begin to lace in the center of the belt, and take much care to keep the end exactly in line, and to lace both sides with equal tightness. The lacing should not be crossed on the side of the belt that runs next to the pulley.

Never add to the work of the belt so much as to overload it.

A good leather belt, one inch wide, has sufficient strength to lift 1,000 pounds.

A Government Ruling on Steel.—Secretary Sherman has sent a letter to the Collector of Customs at Boston, Mass., in which the vexed point of how Simens-Martin metal is to be taxed, is disposed of. He writes: "The Department has again had the matter under consideration, and has submitted the question of the character of the metal to experts, metallurgists and the most prominent manufacturers of and dealers in iron and steel in the United States. A careful consideration of the reports and opinions of these persons satisfies the Department that the Martin-Simens process was intended to be, and is essentially, a steel-making process, and that the product of such process must consequently be steel or an article possessing the general characteristics of steel, and used for the purposes to which steel is applied. In confirmation of the correctness of this view, it may be stated that the classification at the port of New York of the metal in question as steel has been accepted without dissent by importers of that city, and that protest against payment of duty exacted on such classification has in no case been made. After a full examination and consideration of all the facts and information bearing upon the question at issue, the Department is of opinion that the classification as iron, of metal produced by the Martin-Simens process, is erroneous, and that all metal produced by that process should hereafter be classified as steel, and assessed with duty accordingly. The decision of the Department of the 14th of July, 1876, hereinbefore referred to, is therefore revoked, and decision 2,025 will be regarded as in full force."

Corrosion of Cast and Wrought-Iron Water Pipe.—The Hessen *Gewerbeblatt* remarks that it is well known that iron rich in carbon is less subject to oxidation than iron poor in carbon. Wrought iron, therefore, exposed to influences which promote oxidation, wrusts more rapidly than cast iron. The very simple experiment of laying samples of both sorts in damp earth and leaving them there for a sufficient time will show the difference in their rates of rusting. The duration of wrought pipe when laid is thus likely to be less than that of cast pipe, and this is proved to be the fact in practice. Commonly speaking, the temperatures of water running through pipes in use is lower than that of surrounding bodies, and the walls of the tube are constantly condensing moisture, which powerfully promotes rusting. In houses or in masonry conduits, where the pipes can be got at and kept protected, by tarring, painting or otherwise, from rust, wrought-iron tubing can be used with advantage; but in earth it is otherwise. An experienced engineer, who has often had to lay wrought-iron pipe in short lengths below ground, has always found them before long more or less destroyed.

Cement for Kerosene Lamps.—The cement commonly used is nothing but plaster of Paris. But this is porous and quickly penetrated by the kerosene. Another cement, says the *Polytechnic*, is highly recommended, which has not this defect. It is made with three parts of resin, one of caustic soda and five of water. This composition is mixed with half its weight of plaster of Paris. It sets firmly in about three-quarters of an hour. It is said to be of great adhesive power, not permeable to kerosene, a low conductor of heat and but superficially attacked by hot water. Zinc white, white lead or precipitated chalk may be substituted for the plaster, but they harden more slowly.

Good Health.

Prevention of Disease.

In a paper read at the Conference of Charities connected with the meeting of the American Social Science Association at Cincinnati, May 22d, by Dr. Nathan Allen, of Lowell, Mass., he made the following observations on a subject of great importance: "By discoveries in anatomy and physiology; by the use of the microscope and the application of chemical science; by careful observation and experiment, a flood of light has been shed upon the nature and causes of disease. Amid all these discoveries and improvements, the main inquiry has hitherto been how to *cure* disease. Scarcely any thing can be found in medical books and journals till within half a century on the subject of *preventing* disease. The first two writers (living in advance of their times) who started some important inquiries in this direction were Dr. John Forbes, in Great Britain and Dr. Elisha Bartlett, in the United States—men distinguished for their independence and originality of thought. Both of these writers predicted with much positiveness that a great reform was soon to take place in the treatment of diseases, and their predictions have proved true. At no period in the history of medicine have there been such discoveries and improvements as within the last thirty years.

"Great advances have been made in ascertaining the primary causes of disease, as originating in filth, bad air, impure water, foul gases, poison from decaying animal and vegetable matter, etc. It has been found, moreover, that the spread and fatality of infectious and contagious diseases can be very much controlled by isolation, by disinfectants, and by a resort to sanitary laws. To carry out these measures in a community, or extensively among a people, it becomes necessary to employ some public agency, and enlist legislation for enacting laws and establishing boards of health. In this way has arisen what is called 'Sanitary Legislation,' or 'State Medicine,' the chief object of which is to *prevent disease*."

Artificial Light and the Eyes.

The *Medical Examiner* discusses the question of what is the best source of artificial light as affecting the eyesight. Very little knowledge of an absolute description is available on this branch of the subject, but it may be laid down as a general rule that flickering lights, and those of great intensity, are the most trying to the eyes. The Argand form of burner affords the steadiest and best light, and perhaps the arrangement which is least trying to the eyes is to be obtained by the interposition of a shade so placed as screen all direct light-rays from the eyes, at the same time that sufficient illumination is obtained as the place required for work. A medium should also be chosen between too little light, on the one hand, and too much light on the other; for, in the first case, the eyes become strained in endeavoring to obtain correct vision, and, in the second place, they become dazzled by the excessive glare. The color of the object to which the eyes are directed is also a consideration. In the pursuit of literary work, for instance, a tinted paper will be found less fatiguing to the vision than if the paper is of a pure white color. Dr. Croft has recently called attention to the question of color as affecting weak or deficient eyesight. He is of opinion that in some cases spectacles fitted with yellow glass afford more relief to the patient than the ordinary provided with blue glass. Much remains to be done in the study of the physiological action of various colored lights, and there effects on health and disease, and a careful investigation would, no doubt, be attended with results which would certainly be of the greatest interest, if not of the greatest practical value.

The Philosophy of Wet Feet.—The *Herald of Health* says that if the feet were habituated to being washed every night in cold water and rubbed thoroughly, and if they were housed in airy boots, which did not cramp them, we should have less of the injury coming from wet feet. Still it is better to keep them dry, and to toughen them by bathing and friction. Otherwise the most serious injury will sometimes result. Laboring men get their feet wet more frequently than any other class, and no doubt while many of them have often done so without harm, yet others are able to point out frequent instances of harm which has come from it, especially when tired, or when very hot and the water cold. The injury comes from closing the pores of the skin, from contracting the vessels and preventing a free circulation, and from abstracting too much heat. Perhaps also the reflex action on the nervous system, and through it on the lungs and other organs, is one of the causes of injury. Our advice, then, is to keep the feet warm and dry, but not to cramp them, and not to make them tender by neglect of bathing or other means.

Adulteration of Cod Liver Oil.—Mr. Khrohn, of Norway, an authority on cod liver oil, says, in an article contributed to the *Pharmaceutische Handelsblatt*, that in Norwegian oils of the first grade there is a liability to substitution of the oil obtained from the so-called hoakjarring, *Seymnus borealis*, a fish sometimes attaining the length of twelve or fifteen feet. As much as two hundred or three hundred pounds are obtained from the liver of a single specimen, and consequently there is a great deal placed upon the market. The oil is bright and free from stearine, and somewhat cheaper than cod liver oil. It is, however, very difficult of digestion, and possesses a peculiar and disagreeable odor. Its low price and good appearance sometimes attract purchasers, who, in turn, pass off the oil for the genuine article.

Water Gas for Heating Purposes.—The *Journal of Gas Lighting* says: An old idea, it seems, has been revived, and it is again proposed to distribute water gas for heating purposes. There can be no doubt that, if a really practicable method for its production on a large scale could be devised, some economy might result from its use; but it would be at great risks. Everybody knows that carbonic oxide, which constitutes a large portion of the gas, is a deadly poison. It is, moreover, odorless, and consequently an escape would not be noticed. There is, therefore, the double risk of asphyxia from its presence, and of explosion in consequence of the mixture of hydrogen.

Injury from Alum in Bread.—The almost general use of alum by English bakers is one of the most fertile sources of dyspepsia, liver and bowel complaints in adults, and of debility and rickets in children. Bad teeth, and their early decay, is another consequence of the daily use of alum in the food. The bone matter (phosphate of lime) of bread, instead of being assimilated by the system, is either wholly or in part converted into a salt of alumina, which is useless and incapable of appropriation.—*Cooley's Cyclopedia*.

The Week.

Wars and rumors of wars, famines, pestilences, fires, cloud-bursts and terrific heat have been the order of the week. To the Indian war is added further fears of a conflict with Mexico. Seward confirms the reports of the horrible famine in China. Tidings come of yellow fever, increasing with alarming rapidity in the South, and of cholera in Japan.

The most important California event of the week has been the arrival of the Chinese Embassy. Next in importance is the opening of the great mining debris trial. In the United States, the total eclipse is most worthy of attention.

In Europe the farce of the Russo-Turkish war is fast drawing to a close. The Russian and Roumanian soldiers are, many of them, going home. The Sultan has signed the Berlin treaty, and Austria is showing herself no laggard in seizing the advantages held forth to her through it. Signs of reviving friendship between Germany and France have been noticed, but perhaps by too sanguine peace lovers. In England Disraeli has, it may be, reached the "full meridian of his greatness," and Hartington, upon whose shoulders the robe of Gladstone seems to have fallen, is urging lack of confidence in the ambitious Premier. The latter has a desperate charge to answer. Disraeli said to the Sultan: Give me Cyprus and I will defend you against Russia, should she claim too much. But Disraeli did not tell the Sultan that Russia had already agreed not to claim that too much. So England pocketed Cyprus, and the price she paid was a promise to defend Turkey against an evil which England, but not Turkey, knew very well would not arise.

The San Francisco Gold Placers.

We noticed in our last issue the reported discovery of gold placers on the Ocean Beach, near Lake Merced. There have been a great many gold "discoveries" made in San Francisco. Gold has been reported to have been found on nearly every hill of any size in the county. Telegraph, Russian, Mission and Potrero hills have at different times been reported to be auriferous and excitements of greater or less amount have been generated at different times. But in no case has any find of value been made. Some 15 years ago the ocean beach was thoroughly prospected, and although gold was found in the black or magnetic sands, it was not in sufficient quantities to pay for working.

Since then, of course, an immense amount of hydraulic mining has been done in the State, and it is not impossible that the out-going tide has so enriched the beach sands as to make them valuable, or it is possible that some sub-ocean quartz ledge has been so acted upon by the breakers as to produce the same effect.

The present discovery was made by John Frazer, an old miner and prospector, who has worked such placers in New Zealand and on the Pacific Coast at various places. Some four weeks ago he began prospecting the sands and found what he regarded as valuable deposits. Since then the whole beach from a mile north of the "Ocean Side House" to some three or four miles south of it has been taken up by various prospectors, among which appear the names of the more prominent of the labor agitators, Kearney, Wellock, etc.

The ocean beach, as most of our readers are aware, is bounded on the shore side all the way from the Cliff House south to about a mile beyond the creek, which forms the outlet to Lake Merced by the sand dunes and hillocks which extend for something over a mile inland. At the point where the cliffs begin again is situated the most thoroughly prospected of the claims. From this point extend high cliffs of soft sandstone whose strata pitch inland at an angle (with the horizontal), of about 30° to 45°. These sand-stone strata are interspersed with occasional layers of a flint-like rock, and sometimes with streaks of a very useless lignite. The apparently richest part of the placer is from the mouth of Merced creek for a mile to the south.

At the prospect hole spoken of before, we took about a handful of the black sand last week, which showed the "color" on washing very distinctly. The gold was in very thin scales, very bright and rounded, and did not present the appearance of having come there by "salting." Much of it was so fine as to float upon the surface of the water used in washing it. It was very difficult to separate from the magnetic sand by washing alone, as the latter had so great a specific gravity (about five), and the gold was so leaf-like that it was practically more easily removed than the sand itself, which was in rounded grains and presented little surface to the water. The gold present amalgamated very readily and completely. Part of the above sample, which had not been concentrated by washing, was assayed by Mr. Reese, of Falkneau & Reese, State Chemists, and gave $25 to the ton.

For the last three days there has been at work, under the direction of Mr. Frazer, a blanket sluice for the purpose of determining whether it will pay to work or not. At the place spoken of, in a little ravine sheltered from the winds, a hole of three or four feet deep and six feet square has been sunk in the sand; this has filled with water. Into this is placed the end of a primitive pump, consisting of a galvanized iron pipe about six feet long and three inches in diameter, in which works a wooden piston rod, with a conical leather bucket attached to one end, and at the other a cross piece for a handle. This pumps a good stream into a wooden box at whose side near the bottom a slit is constructed, letting a continuous shut of water play upon the perforated iron plate of about two feet square, upon which the magnetic sand is placed; this as it is washed through runs down a blanket sluice for about six feet, the tailings are deposited below and the water runs back into the sump to be used over again. It is claimed that the blanket saves nearly all the gold, as the tailings show only a trace of gold. It is expected that to-night (Wednesday) a clean-up will be made, the blanket washings will be amalgamated, and it will be determined whether or not the claim will justify further labor. If it pays two dollars a day it will be continued, if not, it will be abandoned.

The prospect hole has been dug four or five feet to "bedrock," the sandstone mentioned. It seems to pay best along the bottom, in little shelves and patches wherever there is an indentation in the bed.

Since the above writing we have seen the result of the clean-up for three day's work with the blanket sluice. Four tons of the magnetic sand were put through in this time. The blanket washings were amalgamated and the retorted gold was shown us by Mr. Frazer. The little pile looked to be quite fine ($00 or 900), and was about $24 worth. This was the result of the labor of four men for three days, and as this gives them their $2 a day for the first rude prospecting, they intend to secure a better supply of water and more extensive sluices, and mean to go into the affair on a larger scale.

The Mining Debris Trial.

The case of James H. Keyes against the Little York Gold Washing and Water Company, limited, and others, has been on trial in the District Court of Sutter county, at Yuba City, before Judge Keyser, during the past week. The plaintiff was represented by George Cadwalader, P. Van Clief and J. H. Craddock, and defendants by S. M. Wilson, A. B. Dibble, James K. Byrne and I. S. & W. C. Belcher. The plaintiff is the owner of about 1,000 acres of land on Bear river, about six miles above its junction with the Feather, and the complainant prays for a perpetual injunction to restrain the defendants, who are engaged in hydraulic mining on Bear river and tributaries above plaintiff's land, from discharging debris from their mines into those streams, to the damage of the plaintiff. The complainant does not ask for damages. The suit is against about 20 mining companies. The complainant alleges that during the last three years said miners have deposited over 20,000,000 cubic yards of tailings into said streams; that the depositing continues at the rate of 8,000,000 cubic yards per annum, and that the deposit will be carried down the channels named to the agricultural lands in the valley, to the destruction of said lands. The answers, which are 17 in number, deny that defendants have damaged the plaintiff at all, and claim that they have acquired the right to discharge their tailings into the streams by reason of custom, usage and prescription. They also claim under the Act of Congress of July, 1866, the right of way for flumes, roads and dumps, and the use of streams for mining purposes.

The case is one of the most important that has been brought in California, and is regarded as a test case as to the question of mining debris. The only similar case heretofore tried in the State was that of Atkinson against the Amador and Sacramento Canal Company, which came up at Sacramento in January, 1877. On appeal, the case was reversed on a side question, and none of the main points were determined. Consequently it can be said that the case now on trial is the initial one of the kind. There is a great deal of interest manifested in the trial. The court-room has been daily filled with persons who are directly or indirectly interested in the proceedings, and the case promises to be lengthy and ably contested. At the opening of the trial, the defendants moved for separate trials. The Court denied the application. The plaintiff then offered his title papers and produced several maps showing the situation of the land in controversy and the adjacent country. The following is in condensed form the testimony of the various witnesses for plaintiff.

J. H. Keyes:

I have known Bear river generally since 1850, and in front of my place since 1856. It was then clear, with abrupt banks about 12 feet high and gravelly bottom. The land was rich, alluvial and productive. There were two classes of bottom land, and higher up was red land. The river at very high stages overflowed the bottom and for a short time, about 12 hours generally. The first perceptible change in the river was in 1862, and it has been continual ever since, so that the original channel has become extinct, and a new one formed in another place. The old channel filled entirely in the winter of 1867-68, and broke across the high red land in Placer county, and ran into Yankee slough. Another channel, called new Bear river, was also formed, commencing at a point where the river leaves the foothills. The river has widened out and changes its position in the channel. My land has suffered from damaging overflows four times in the last three years. The deposits in the house and on the land did not dry for two or three months so that I could walk on it. The deposits affected the value of the land materially and destroyed its productiveness. I have not been able to use the land successfully for two years. I formerly raised 50 or 60 bushels of barley to the acre, and 30 or 40 bushels of wheat. Last year it raised less than 10 bushels of wheat and this year not over five.

The land covered by heavy material failed to produce wheat. About 300 acres of the land is covered deeper than I plow—about 10 inches.

Bear river runs promiscuously all over the bottom, shifting around and overflowing land formerly high. I made an effort to protect my land, and have spent $12,000 or $15,000 in leveeing. The overflows have rendered the land disagreeable to live upon. The water which came on in 1875-6 was tested and found to contain about one-third of its bulk sediment. Some of my land was filled above the fences, and they had to be raised and reset. The water in the river has been growing muddier, and the deposit of sediment in its bed greater each year, and, consequently, the danger to the valley lands is increased. The levees have to be increased in height about two feet each year. They are now about four and a half feet above the sediment, and I do not consider them safe if they are not heightened. I will probably be overflowed next winter, and my entire levee destroyed. It should be made about three feet higher than high water mark to be safe. The railroad bridge over the river has been raised about two feet. The town of Wheatland is on red land, and I judge that the river channel is now three or four feet higher than the land at Wheatland. There has been a quantity of small stones deposited on my land. They are about the size of shot. When the mines above are shut down the water of the river is comparatively clear at my place. I attribute that to their stopping work. When their operations are resumed the water becomes muddy again. I have noticed that fact several years. This comparatively clear water can be used for irrigating and stock, but the muddy water is destructive to vegetation when used for irrigation and unwholesome for stock. The first freshet that comes each season is of clear and useful water, but the succeeding ones are muddy. I have noticed that fact for ten years. The sediment is productive alone of willows. Water of the river above the mining dumps is clear.

In cross-examination Keyes testified that, this year 100 acres of wheat planted on the sedimentary land will not yield five bushels to the acre. Have corn planted on the same land. It promises big stalks, but no ears. Potatoes produce large tops, but small potatoes. The average depth of deposit on the corn patch is two and one-half feet. Have other corn patches on thinner deposit, but it is unsuccessful. Planted it six or seven years and got nothing. Last year raised 18 tons of potatoes on 12 acres of sediment land. The land was not good for potatoes originally, and is worse now. Two years ago raised some beans, and have some in now. They are not very successful. Have 14 acres of alfalfa on land with three feet of sediment. Pastured 7 cows, 20 sheep, about 40 hogs, and about 3 horses on it one season; but the top roots rotted—too much water—and it died out. Think mining debris absolutely destroys the productive quality of agricultural land. When it is covered so that the plow will not go through it, I consider it worthless. I rented some of my sediment land for $8 an acre this year, but the tenant will lose $75 or $100. Think that the failure of the land to mature corn is because of a lack of moisture. Put in some in grain in 1875, after it got dry enough. The barley produced 8 or 10 bushels to the acre, and wheat was almost a total failure. The sedimentary land has a tendency to become foul with willows. It is difficult to keep them down, and hardly anything else will grow.

C. P. Berry, Speaker of the last Assembly, testified: Have resided about four miles from the mouth of Bear river since 1857. Am engaged in farming. Am familiar with Bear river up to the railroad crossing. Have known Keyes to be occupying his land since 1858 or 1859. He has been farming it like the rest of us. Think the Bear river has run over pretty much all his land, as it has over the other lands in the Bear river valley. When I first knew Bear river, in 1857, the water was clear and run in banks of natural earth 10 or 12 feet high. The channel was clear and well defined. Keyes' land was overflowed in 1875. The filling of the river caused the water to flow over a ridge into a slough. The bed of the river became filled with slickens. It left in places sand banks, and in others fine mud. Do not think the deposit is at all calculated to add to the fertility of the land. Have the same character of slickens on part of my land, and I have never since tried to use it. I deem it almost worthless. The deposit dries and cracks, and the land could not be used unless it was pulverized. Have abandoned my sediment land since 1862. Have run a levee to leave it out, since it benefits me only by producing willow and cottonwood for firewood. It overflows every year. I consider the deposits very deleterious. Think between 8,000 and 10,000 acres of land have been destroyed in Bear river valley by deposits. Have observed that in summer after overflows we have more sickness; think it is caused by the deposits.

A. L. Chandler testified: I have farmed near Bear river since 1855. Have been familiar with that river since 1852. Was at Keyes' house just after the water went down in 1875. Found mud two feet deep there. The mud was nearly up to the floor of the house. Know that the soil had been very fertile prior to the overflow, and had raised from 40 to 50 bushels of barley per acre and 30 to 40 of wheat. It was black, alluvial, first-class land. Consider it almost entirely ruined by the deposits.

James Harrison testified that he resides in Placer county, near the junction of Bear river and Greenhorn, and has lived there 22 years. He mined on Bear river from 1856 to 1861; then took charge of a portion of Bear river ditch, about 14 miles long. Up to 1862 there was no sediment of consequence in the water. About two years ago he tested the water and found about one-fourth solid matter in suspension. He knew that large quantities of sand, etc., pass over the ditch dam down the river. The water of the ditch is settled by several reservoirs in the mountain gorges. Reservoirs about 180 feet long by some 90 wide, and 25 feet deep. The reservoirs have sluice-ways at the head of the ditch to remove deposits from the water. He sluiced out the reservoirs about three times a week. The reservoirs would fill up with slickens in one day, and heavy sand would sink through to the bottom. The water in the river gets low and clear comparatively about August. I have seen heavy stones in Bear river 12 or 14 miles below Greenborn, which came down since 1861. The water in the early freshets carries down more sliekens, but is by no means clear. It could not be used for domestic purposes or for animals. There is very little difference in the water of succeeding freshets.

D. A. Ostrom, Assemblyman from Yuba, testified: Have been a farmer since 1852; now reside in Yuba county; lived from 1853 to 1867

in Sutter county, a mile above plaintiff. Worked the land in controversy at times till 1860. It was originally first-class sandy alluvial; cut 80 bushels of barley to the acre on Keyes' ranch in 1860. Noticed a large deposit made in 1875 and 1876; when on the ranch last week noticed that land formerly the most productive was now entirely destroyed; several hundred acres are destroyed. Think the deepest deposit 10 or 12 feet deep; have seen sand drifted up like snow; have never raised a good crop on the land with any considerable sediment. Where we cannot plow things will not produce; think the effect disastrous, to put it mildly, to Keyes' land. Have seen poor crops on his ranch since 1875—hardly worth cutting. I attribute this result to the debris. The population outside of Wheatland has decreased on the Bear river about one-half since 1862. There are now about 150 persons living on the river, and 200 or 300 in Wheatland. River water has been muddy since 1862; the water was origiually clear; it is becoming muddier annually; never noticed extensive filling till 1861-62. The river banks at first were from 10 to 14 feet high, with a pebbly bed. The channel in 1867-68 at Johnson's crossing filled about 10 feet, and six miles lower down two to five feet. It is bottom land a mile and a half wide at Johnson's crossing; the deposit there is from high land to high land. Keyes' land is nearly destroyed for grain raising. The water of the river is unfit for use for house and stock; never tested it for irrigation. Do not think it good, as it would leave a sediment poisonous to vegetation. Very few trees in Keyes' orchard are left. His corn looks very well. Don't know how it will produce.

Thos. Brewer, Sr., testified as follows: Have been engaged in farming on Bear river since 1852; have known the land owned by Keyes since 1856. When I went there the water in Bear river was clear; debris and sand have covered most of Keyes' land; before his land was covered it would produce from 30 to 40 bushels of grain per acre; it had been damaged by overflow and sediment three-fourths of its value. The water was more clear in November, when the first freshets came; the channel has been filling gradually every year, and the deposits of sediment prevent successful cultivation of the land. The crops grown by Keyes during the past few years have not been good; Keyes and myself built the levees to keep the water and debris off our lands; we commenced building them at the foothills, and continued along down; first built them seven feet high; without them our land would be of no value to us for farming. Keyes and myself bought land to get the right of way along the river above us to build our levee on; the owners would not join us and we had to buy them out. In the first year of my residence on Bear river I saw hundreds of salmon in the water, and killed 17 in two hours with a shotgun. During the past 16 years have not noticed any at all. We paid between $18,000 and $20,000 for the right of way for levees. The old levees would not answer the purpose, and we had to build new ones.

W. D. Armisted did little more than corroborate previous testimony.

Henry Haile testified that he was a farmer by occupation; lives on Bear river; knows the Keyes land and the condition of the crops at the present time; they were very poor crops; have tried to grow crops on similar land, but with poor success. The road along Keyes' land in 1876 was almost impassable on horseback; knew a man to get down in mud in January, 1876, and could not get out; he cried for help and I went to his assistance; think he would have died if he had not been assisted, as he was nearly exhausted.

Dr. D. P. Durst said: I live on my farm on Bear river. Have seen the deposit on Keyes' land made in 1876. This debris has the effect to destroy the crops and plants.

William Singer, an officer in the United States Land Office at Marysville, was called to produce a letter and the record of the office as proof of the listing of a certain part of Keyes' land by the Department of the Interior at Washington. Wilson, of defense, objected to receiving it, as not being an original document, but a copy. The question was argued at length by both sides, when the Court decided that it should be received for what it was worth, subject to a conditional objection in the future.

S. D. Wood, a farmer on Bear river, repeated the same story as the previous witness, Durst. He had tried the water for irrigating his land, but it left a crust on the soil and closed the pores, doing more damage than good.

R. H. Huff, a farmer on Bear river, told his story, which did not vary much from those preceding him.

C. A. McCullough said he had worked about four years as a miller at McDonald's mill, on Bear river, about six miles above Wheatland. The sedimentary deposits filled up the ditches carrying the water to the mill, and sluices had to be constructed in several places to clean them out. They run the mill several years until about 1876, when the old wheel had to be cut out. The deposits had filled up around it so as to make it impossible to run longer.

Cyrus Stoddart corroborated the main points of the evidence of the previous witness.

P. E. Drescher testified that he was a farmer and surveyor, and was well acquainted with Bear river, and gave his observations and figures of measurement taken at different points along the river, and also of borings on different sections of Keyes' land. The testimony occupied much time, but really did not throw much new light on the subject. In cross-examination he stated that he thought the bed of Bear creek at Steep Hollow had raised from 60 to 75 feet since 1849.

Col. T. B. Ludlum testified: I am here in the interest of defendants. I know the hydraulic mines on Bear river, described in the complaint. The gravel bed of the mines is from three-quarters of a mile to a mile and a half wide from the outer edges of side wash. This auriferous earth is composed of sand, quartz, slate and trap boulders. Some sections have pipe clay.

Ludlum said he had seen the various claims mentioned in the complaint which dump into Bear river or its tributaries. The Cedar creek claims use about 2,400 inches of water. He described the points at which the claims dumped. More water was used at times, which did not go through the pipes. The Polar Star had two pipes, with about six-inch nozzles, and used about 1,500 or 1,600 inches of water. The Elmore claim used 850 or 1,000 inches. Staples Bros. used about 800 inches; the Pine Top mine, about 500; Dekamp, about 300 or 400; the Boston claim used the same amount. Do not know how much other claims use. They all run from four to nine months of the year, between March and September. Most of them are hydraulic mines. Never estimated the amount of earth moved in a day by one inch of water, but it is from two to six cubic yards—that is, in 24 hours. The companies named worked from 5 to 24 hours daily.

Van Clief asked from what source the water used in the mines came, and proposed to show that it really all came from sources whence naturally it never would reach the river. The Court ruled the testimony out, on objection.

Witness—The river is about one-third of a mile wide opposite Dutch Flat. The two claims farthest removed are nine miles apart. The several claims spoken of in the testimony are worked independently of one another, and the companies are not connected. Do not know how much matter any mine has discharged. Many days no water is used in the several mines. About three yards of heavy material is removed daily at the Polar Star in the washing season. The water is comparatively clear above that mine. All the mines mentioned in the complaint dump their tailings on land possessed by them.

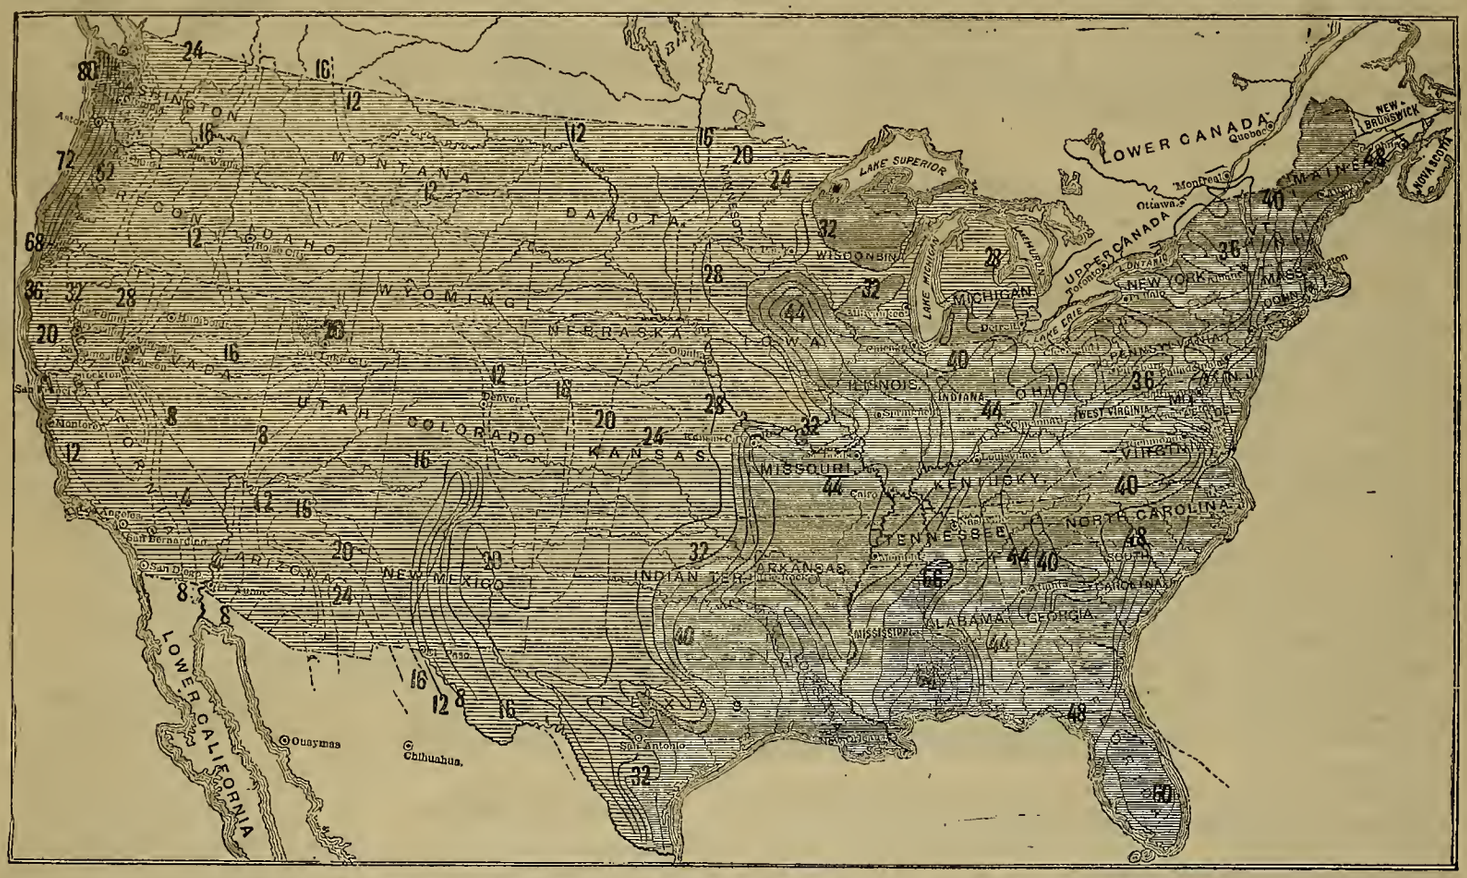
W. F. Peck testified that he was a surveyor. He was with the Drescher party which explored the river recently. He produced 14 bottles of water taken from the river and tributaries at different points; also sediment from plaintiff's land. His testimony was generally the same as that of Drescher.

METEOROLOGICAL SUMMARY FOR JULY.—The report of the U. S. Signal Service officer, of San Francisco, for the month of July is summarized as follows: The mean hight of barometer for the month was 29.90; mean temperature, 57.8; mean humidity, 76.09; prevailing winds, southwest; highest barometer, 30.027; lowest, 29.38; highest temperature, 73°; lowest 51°; monthly range, 22; greatest velocity of wind, 32 miles per hour; total number of miles traveled by wind, 9.183; total rainfall, .01 inches. Rainfall in July during former years: 1872, .01 inches; 1873, .01 inches; 1874, .00 inches; 1875, .00 inches; 1876, .01 inches; 1877, .02 inches.

AN AGENT IN WISCONSIN.—Mr. W. D. White, who has been agent of the PRESS in San Bernardino, has gone to Appleton, Wisconsin, where he will remain for several months. Mr. White will represent our publications in Wisconsin, and we recommend him to the reading public who may desire information concerning California industries.

The Distribution of Water in the United States.

Although we are in the midst of summer's drouth and have neither fear of rain nor desire for it, it may not be improper to present a few general remarks on a moist subject. We give on this page a map of the United States, drawn to represent different conditions of rainfall in the different parts of the Union. It will be seen that there are all quantities from almost nothing up to perpetual drenching, and that in the same latitude there are most wide differences in the rain supply. It has always been a stumbling block in the way of the encyclopedia writers to describe the climate of the United States, and naturally so, for, as says a writer in Johnson's, to speak of the climate of the United States would be misleading. Nothing can be said of the United States, as a whole, in respect to temperature, humidity or force of the winds. The United States, owing to its vast extent in latitude and to the influence of great longitudinal chains of mountains, has many climates. The annual rainfall ranges from 72, 80 and even 100 inches upon the upper Pacific slopes, to 12, 8 and even 4 inches only on the great interior basin, between the Rocky mountains and the Sierra Nevada. The annual precipitation of rain and melted snow is greatest on the Pacific slope of the Sierra Nevada and on the Coast range above the 42d degree. Below this the annual precipitation is reduced to a low average and occasional drouths result. Speaking generally the entire Atlantic slope is well watered, the average rainfall ranging from 32 to 56, and more, inches. Of the Mississippi valley, the eastern side receives an abundance of rain, though the southern portion, especially in Mississippi, is the most liberally watered. From the Mississippi westward the rainfall runs down from an average of 44, 40 or 36 to an average of 20, 16 or 12 along the 100th degree of longitude.



MAP OF THE UNITED STATES, SHOWING THE AVERAGE RAINFALL IN INCHES AT DIFFERENT POINTS.

The differences in amounts of precipitation, aside from the general laws of rainfall, are obviously occasioned by local conformations of the surface and their relation to moisture-bearing winds. These affect not only the times of rainfall, but also its aggregate amount. Thus while southern California has but an average of about 10 inches, the lower States of the Mississippi valley, under the same latitude, has no less than 50 or 60 inches. San Francisco has an average of 23 inches, while Atlantic States in the same parallel have 42 inches.

Of the special causes producing a different condition of rain fall on this coast and in the Mississippi valley, Prof. Arnold Guyot remarks as follows: "The amount of rain on the Pacific coast increases northward and the regime of winter rains goes far beyond its natural limits to the 40th degree of latitude; while in the east the amount of rain decreases toward the north according to the general law. This remarkable anomaly in the rains of the Southern States is explained by that vast indentation forming the

(Continued on page 77.)

The Mechanics' Fair Daily.

By authority of the BOARD OF MANAGERS OF THE MECHANICS' INSTITUTE FAIR the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the NINTH VOLUME of the MECHANICS' FAIR DAILY during the THIRTEENTH INDUSTRIAL EXHIBITION, which opens in San Francisco, Thursday, August 13th, 1878.

It will be of large size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, a list of exhibits, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resources and rapid progress of our great Western community.

More than ONE HUNDRED THOUSAND different individuals will read copies of our paper during the Fair. The novel character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle by those who receive it freely at the Fair, make the paper a powerful advertising medium.

The Managers have granted us the exclusive advertising and printing privileges, and will receive no advertising in the official catalogue and reports.

Our eight previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a more broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our Coast.

DEWEY & CO., Publishers.

Office, MINING AND SCIENTIFIC PRESS, No. 202 Sansome street, N. E. corner Pine, San Francisco.

IONE VALLEY, Cal., January 20, 1878.

MESSRS. DEWEY & CO.—*Gentlemen:*—I received my patent last night, and was glad to find that you were so prompt in the matter. I am pleased to give you the credit due you for the faithful and honorable manner in which you have discharged your duty in getting my patent. I shall hereafter recommend you to the public as having discharged your duty with honor. Yours, etc.,

W. W. CARLILE.

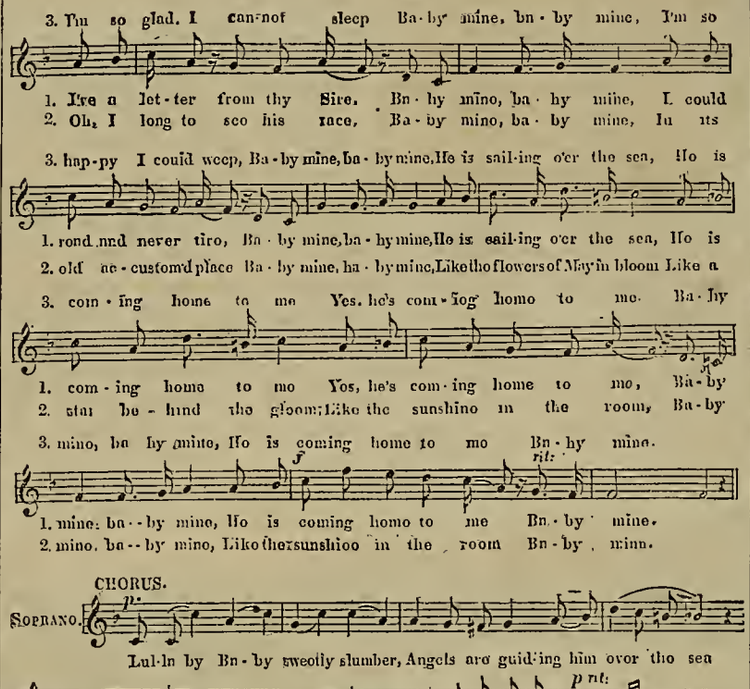
PACIFIC RURAL PRESS,

A first-class 16-page Illustrated Agricultural Weekly, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Send for a sample copy.

DEWEY & CO., Publishers, S. F.

A POPULAR SONG AND CHORUS.

"BABY MINE." *—By Herbert Smith.



3. I'm so glad. I can not sleep Ba-by mine, ba-by mine, I'm so
1. I've a let-ter from thy Sire. Ba-by mine, ba-by mine, I could
2. Oh, I long to see his face, Ba-by mine, ba-by mine, In its
3. hap-py I could weep, Ba-by mine, ba-by mine, He is sail-ing o'er the sea, He is
1. rond and never tire, Ba-by mine, ba-by mine, He is sail-ing o'er the sea, He is
2. old ac-custom'd place Ba-by mine, ba-by mine, Like the flowers of May in bloom Like a

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form; all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco.

UNIVERSITY OF CALIFORNIA.

The August examinations for admission to the Colleges of Letters and of Science, will be held at Berkeley on WEDNESDAY, THURSDAY and FRIDAY, August 7th, 8th, and 9th, each day, at 10 A. M.

The University year begins August 8th. By order,

M. KELLOGG, Dean.

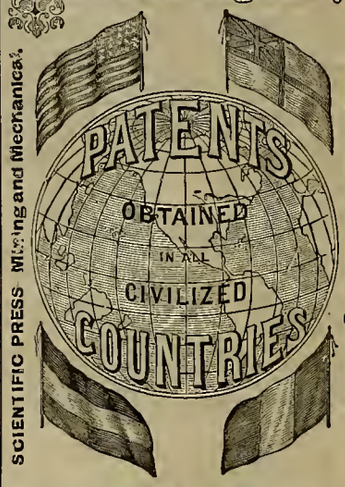
DEWEY & CO'S SCIENTIFIC PRESS Patent Agency.



Office—202 Sansome St, N. E. Cor. Pine, S. F

PATENTS obtained promptly; Caveats filed expeditiously Patent re-issues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing.

The shrewdest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

ST. CHARLES HOTEL,

SANTA CRUZ, CAL.

JOSEPH BLOCH, - - Proprietor.

This popular House, having been thoroughly refurnished and refitted, is now open for the reception of guests as a

FIRST-CLASS HOUSE,

And in the character of its accommodations second to no interior Hotel in the State.

The Hotel Coach will carry passengers from all Trains and Steamers to the House

FREE OF CHARGE.

Two lines of Street Cars pass the Hotel to the beach and Bath Houses.

ANDERSON SPRINGS,

LAKE COUNTY, CALIFORNIA.

Nineteen miles from Calistoga, five miles from Middletown, and ten miles from the Great Geysers; between which and Anderson Springs there is a daily line of Stages.

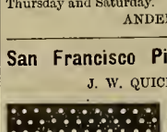
Hot Sulphur Water for Rheumatism, Paralysis, etc.; Cold Sulphur for Dyspepsia, Diseases of the Stomach and Bowels. Scenery unsurpassed. Climate mild and equable. Consumptives generally improve in health, and asthmatics are invariably relieved. Trout Fishing on the grounds. Deer Hunting in the immediate vicinity. Accommodations and Cookery good. Board from $10 to $12 per week.

Take the Lakeport Stage that leaves Calistoga, Tuesday, Thursday and Saturday. Fare to Anderson Springs, $3.50.

ANDERSON & PATRIQUIN, Props.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,



Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco

HOME IN THE COUNTRY!

NOOK FARM.

Families wishing to spend the summer in the country will find this a cheerful home, and beautiful scenery of such endless variety as tempt to healthful exercise and recreation. We furnish good accommodations and an excellent table. Good fishing and hunting on the premises. Two trains from San Francisco, per Vallejo and Napa Valley Railroad, pass the Station daily.

Address, E. B. SMITH, Rutherford, Napa County, Cal.

THE O'HARRA

CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:

One man, per day	$ 3 50
One man, per day	3 00
Wood, 1½ cords at $3	7 00
Cost of 20 tons	$13 50
Cost of one ton	67½

From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address:

JUDGE WM. WEBSTER, Paymaster Mine, Reno, Nev.
LEWIS CHALMERS, Manager Exchequer and IXL Mines, Silver Mountain, Cal.
J. S. CONE, Vice-President Tehama County Bank, Red Bluff, Cal.

KING ENGINE.

The Only SAFE BOILER.

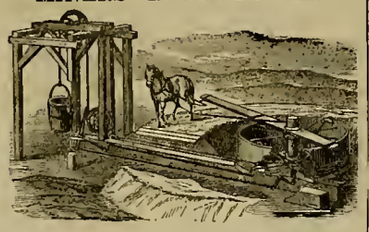
SAVES One-half the FUEL Consumed by Others.

The engine is adapted to all the various industries in which small power is required. The engines are FIRST-CLASS, and are made from two to twelve horse-power.

The smaller sizes are especially recommended for irrigating land, driving printing presses, or manufactories. The larger sizes are being extensively introduced in small quartz mills, where their economy of fuel and portability especially commend them. Send for circular.

REYNOLDS, RIX & CO., Sole Agents,
18 & 20 Fremont Street, San Francisco, Cal.

MINERS' HORSE-POWER.



This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS, RIX & CO.,
18 & 20 Fremont Street, San Francisco, Cal

FIRE! FIRE!! FIRE!!!

ENGINE FOR SALE.

A first-class, large sized Britton Fire Engine, in fair order is offered for sale cheap. Price, $400. It is worth more than double that sum. About forty men can work on the brakes. Towns or corporations wishing a good machine should examine this engine before ordering elsewhere. Apply to

MECHANICS' INSTITUTE.

13th INDUSTRIAL EXHIBITION.

SAN FRANCISCO, CAL., 1878.

The Managers have the honor to announce to the public that the Thirteenth Grand Exhibition of SCIENCE, ART and INDUSTRY, given under the auspices of the Mechanics' Institute, will open at the Pavilion on Market, Eighth and Mission streets, on

TUESDAY, AUGUST 13th, 1878.

Great and unusual attractions will be presented to visitors. Mining, Agricultural and other machinery will be in motion. Pacific Coast Manufactures, Minerals and products of the soil will be fully represented, beside many new and interesting novelties never before exhibited on this Coast. The

ART DEPARTMENT

Will be under the supervision of the San Francisco Art Association, a guarantee for excellence and completeness. Local Art will be specially represented, as also works of noted foreign artists, selected from the private galleries of this City. The

HORTICULTURAL GARDEN,

So popular heretofore, will be made still more attractive this year by the addition of many new features.

THE MUSIC.

Each afternoon and evening a first-class instrumental concert will be given by the best soloists and accomplished musicians of this City, with a daily change of programme of the best and most popular music.

No expense or pains will be spared by the Management that will add to the comfort or convenience of visitors.

Applications for space or information can be obtained from the Secretary, at the office, 27 Post street.

LAND! BOUNTY!! PENSIONS!!!

PATENTS!

Do you want to buy, sell or exchange lands or other property in any part of the U. S. or Canadas? Are you a Soldier or Sailor, in want of a Patent? Why not obtain more Bounty or Pension? Do you want to locate Government or State Lands without settlement? Why not? When I have the well-known Approved Soldiers' Additional Homesteads, under seal of the General Land Office, and that can be located without settlement, upon any Government $1.25 or $2.50 lands, subject to homestead. The Sioux Half-Breed Scrip, for location upon unsurveyed lands.

Land Warrants and Scrip of all Kinds

For cash, or part on time. Good title given or no pay. Have you any lands with an imperfect title to sell, or choice vacant lands you know of which could be located to advantage; or claims not lawfully held, which we could contest. Let me hear from you in full, and I will do my best to inform you what is to your advantage.

I will mail you a circular explaining all, and a copy of the new Pension Law. Address, (plainly)

D. H. TALBOT,
General Land, Scrip and Warrant Broker, SIOUX CITY, IA.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Mining Share Market.

The mining share market for the past week has been pretty active, as compared witb recent operations. Attention has principally been turned to Ophir and Sierra Nevada. The Ophir has been opened to stockholders, some of whom bave examined the mine, and great interest is manifested in expected developments. Mr. Patton was present and escorted the visitors through the undergrounnd regions of the mine. The route was by the vertical sbaft and cages to the 1500 level, thence by the incline and giraffe to the 2000 level, crosscut No. 2 being at present the graud point of interest. Our route laid through the drift rnn from the main incline to the bottom of the winze that comes down from the 1900 level, and now known as crosscut No. 1, at a point 50 feet west of wberc the ore body was cut. At tbe bottom of the winze just mentioned a drift was started to the northeast, known as the northeast lateral drift. This drift extends to the northeast a distance of 100 fect in a direction supposed to be parallcl with the ore body. Tbe feeder or cross-bourse contains some good ore, and is richest where it is about one foot in width, a short distance before reaching the main ore body. The main ore body is reached at a distance of ahout 75 feet from the northwest lateral drift. The whole length of crosscut No. 2 is about 80 feet. Therefore, it has penetrated the ore body a distance of about seven feet, that is, measuring on the south side. The course of tbe ore body is northeast and southwest, though it seems now to be bearing considerably to the east. The appearance presented at the face of the drift is that they are just now in the west side of the ore body. The ore is still of low grade and much mixed with porphyry, but it is likcly to be found much bctter as the crosscut is advanced. An evidence of this is the fact that in the south side tbe ore is best, and is the least mixed with porphyry. Altbough presenting all the characteristics and mucb the same appearance as when cut by crosscut No. 1, the ore bere as far as explored is of much poorer quality. From wbat was to be seen not much more is known of what the ore body really is at crosscut No. 2 than was known before. It is still to be cut through, the west side having been but fairly entered into. Opinions expressed are said to be favorable.

Our usual summary of news from the Comstock did not come to hand in time for this week's issue, and is therefore omitted.

Continued from page 73.

Gulf of Mexico, which, like a great boiler, supplies the return trade winds that prevail throughout the summer with a large amount of vapors. These fall in copious showers on all the eastern portion of the United States, increasing considerably the total amount of rain and entirely obliterate the dryness of the summer, which usually characterizes the climate of these latitudes. If the regime of winter rains extends farther than usual in California, it may be traced to the influence of the great heat generated by the south western plateaus, which rotards the condensation of the vapors from the Pacific until tho winds have reached a higher latitude, and to the absence of polar winds, which are turned away by the Rocky mountains." Of the special influence exerted by mountain ranges on this coast, it may be said that the high border chains from Oregon to the Alaska Peninsula, which bend like a gigantic arm, catching the retnrn trade winds of the Pacific, receive an amonut of rain greater than any part of the continent, while tho east side of these mountains has but a stinted share of the precious element. It is a remarkable fact, noted by Guyot, that tho Appalachian system does not increase thu condensation of rain, as mountains usually do. This is doubtless due to their extending parallel with and not transversely to the winds bearing rains.

We have thought that a map like tbo ono on page 73, showing approximately the amount of rain in different parts of our country, would be of valuo to our readers in any comparisons which they may desire to mako. Therefore, we have drawn and engraved tho one which appears on this page, compiling it from the official drawings of the Smithsonian Institute. It will be noticed that tbe map is shaded somewhat, according to tbe weight of tbo rainfall, and that the figures give the average annual amount in inches within each area enclosed by the dotted lines. Of course it does not follow that amount of rainfall is aloue the test of the productive power of a region. "Euough is as good as a feast," and our California average in some parts of the State is far preferable to the excess and unreasonableness which embraces agricultural operations iu somo other parts of the Union.

Government Surveying on this Coast.

Among the overland passengers we notice tbe names of Lieut. Wheeler's engineering corps, who are now arriving to begin a system of accurate surveys of different portions of Pacific coast territory. From exchanges we learn that the main stations to be occupied astronomically are Fort Seldon, N. M.; Fort Bliss, Texas; Tulare, California, on the Southern Pacific railroad; the Dalles, on the Columbia river, and Walla Walla, in Washington. Party No. 2. of the Utah section, instead of continuing its labors from Fort Hall to the north and westward as was at first intended, has been transferred to California, along the Sierras to tbe Coast Range southward from Bakersfield, and from Los Angeles toward San Diego. Party No. 3. of this section will continue the triangulation from an astronomical station at or near Visalia, through the Sierras, to join the triangulation brought from the base of Virginia City, and that developed in 1875, from the base of Los Angeles, to the north and eastward.

The astronomical parties carry out their observations in pursuauce of the methods adopted by the survey at the given poiuts. The total area proposed to be occupied during the season of 1878 will be approximately 40,000 square miles. The whole work is in pursuance of plans proposed by Lieut. Wheeler, in April, 1872, approved by the Chief of Engineers and Secretary of War, and adopted by Act of Congress in June of that year. This plan had for its object the prosecution of a thorough detailed and economic topographical survey of the territory of the United States west of the one-hundredth meridian, embracing 1,443,360 square miles.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Standard, July 22d, $37,221.77; Northern Belle, 22d, $8,199.98, 24th, $8,067.15; Star, 22d, $2,821—total to date, $20,222; Manbattan, 22d, $2,851, 24th, $12,300; Tybo Con., 22d, $4,794.20, 24tb, $4,409.04—total to date, $45,121.25; Christy, 29th, $4,394.00; Modoc, 25th, $2.259.78—total to date, $22,079.59; Stonewall Jackson, 27th, $17,000; Independence, 29th, $8,000; Leopard, 26th, $6,844.86; California, 27th, $183,637.78; Cou. Virginia, 27th, $66,049.83; McCracken, 27th, $25,955.21.

IN Minnesota on July 30th a hail storm did much damage to crops. Stones four inches in circumference fell, covering the ground to a depth of three inches.

Woodward's Gardens were never more attractive than at present. Besides three lions already mentioned, six monster living alligators, several iguanas and a boa-constrictor have just been added. New stars are constantly engaged for the Pavilion exercises. Rates of admission as usual.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.04. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

MODEL MAKER AND MACHINIST.—I. A. Heald, No 514 Commercial St., San Francisco, (fourth floor).

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore.

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sen through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the sams.

Excelsior Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Potosi District, Lincoln County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Seventeenth day of July, 1878, an assessment of Twenty-five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at the office of the Company, 304 Post street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 20th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the Sixth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

FRANCIS P. DEVINE, Sec'y.

Office, 304 Post street, San Francisco, Cal.

Mariposa Land & Mining Company of California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given that at a meetiug of the Board of Directors, held on the Tenth day of July, 1878, an assessment (No. 14,) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office No. 2 Nassau street, New York City, N. Y.

Any stock upon which this assessment shall remain unpaid on the Twelfth day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and the expenses of sale. By order of the Directors, LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, 309 Montgomery street, San Francisco, Cal.

Orion Mining Company.—Location of Principal Place of business, San Francisco, California. Location of Works, Iowa Hill, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of July, 1878, an assessment, No. 2, of 70 cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 28 Sansome Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 9th day of August, 1878, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Saturday, the 24th day of August, 1878, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors.

P. CONKLIN, Sec'y.

Office, No. 28 Sansome Street (up-stairs), San Francisco, Cal.

Seaton Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Drytown Mining District, Amador County, California.

NOTICE.—There is delinquent upon the following described stock, on account of Assessment (No. 11) levied on the 26th day of June, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Thompson, W., Jr.....	72	15	$1125 00
Thompson, W., Jr.....	70	10	750 00

And in accordance with law and an order of the Board of Directors, made on the twenty-sixth day of June, 1878, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Company, Room No. 58 Nevada Block, northwest corner Pine and Montgomery streets, San Francisco, California, on Wednesday, the twenty-first day of August, 1878, at the hour of one o'clock P. M. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.

JOEL F. LIGHTNER, Sec'y.

Office, Room No. 58 Nevada Block, Northwest corner Pine and Montgomery streets, San Francisco, California.

Office South Comstock Gold and Silver Mining Company. Notice.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of Trustees and the transaction of such other business as may be presented, will be held on Monday, the 19th day of August, 1878, at two o'clock P. M. of that day, at the office of the Company. Transfer books will be closed on Saturday, August 12th, 1878, at the hour of 12 M. of that day.

J. M. BUFFINGTON, Secretary.

Office—Rooms 3 and 4, second floor, No. 309 California street, over Aetna Insurance office.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Seventeenth day of July, A. D., 1878, an assessment, (No. 4,) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of said Company.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, A. D., 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tenth day of September, A. D., 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. J. W CLARK, Sec'y.

Office, No. 313 Pine Street, San Francisco, Cal.

Telegraph Copper and Silver Mining Company. Principal place of business, City and County of San Francisco, California. Location of works, Gopher Mining District, Calaveras County, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of July, 1878, an assessment of three (3) cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at his office, Room 2, 528 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 13th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth (9th) day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

I. T. MILLIKEN, Sec'y.

Office, Room 2, 528 California street, San Francisco, Cal.

REGISTER YOUR

TRADE

MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

DEWEY & CO., Patent Solicitors

No. 202 Sansome Street, S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,

(Of the San Francisco *Evening Post.*)

This volume is now ready. It is a large 12mo of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loop, at Tehachapa Pass, on the S. P. R. R.; Yuma, Prescott, Phœnix, Florence, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tunuacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains. Calabazas, in the valley of Santa Cruz; Mormunacion Peak, the Arlave Valley and the ruins of Casa Grande.

Also, numerous other engravings of mines and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the McCrackin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for $2 each.

HINTON'S NEW MAP OF ARIZONA,

Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, $2.50 each; in covers, $1.50 each. For sale by

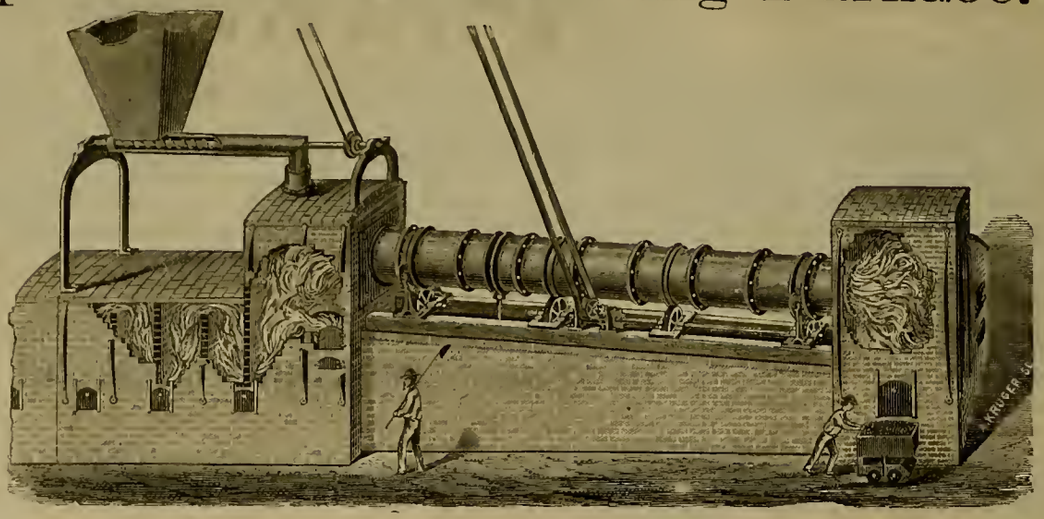
ROBERT M. CONE, 226 Fremont St., S. F.

At the Old Stand, Market Street, head of Front, S.F.

Howell's Improved White Roasting Furnace.



This cut represents the most improved construction of this unrivaled Furnace, the superiority of which, over all others as regards cost and capacity, as well as the economical and thorough oxidization and chloridization of ore, is now generally conceded.

In this Furnace, as covered by the Howell and White patents, are combined the three acknowledged requisites for the thorough and economical roasting and chloridization of ores.

First.—Continuous progression through and discharge of the ores from the furnace—while in the meantime they are, by being constantly showered through the heated air and gases within it, exposed in the greatest possible degrees to their reducing action.

Second.—Subjecting the ores to this showering process any length of time that may be necessary, according to the character of the ore, for its thorough reduction. In passing through the furnace it ordinarily falls about 1,000 feet, all the time in direct contact with the flame.

Third.—Increasing the heat on the ores as they are progressed through the furnace.

In this respect this furnace excels all others, as in none of them are combined all these essential requisites. It will chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade

The first cost, as well as the cost of operating it, is less than that of any other furnace of equal capacity.

It requires no especial skill in management that cannot be readily acquired by any one capable of conducting an ordinary silver mill.

We manufacture various sizes adapted to a five, ten or twenty-stamp mill, and will furnish plans by which any competent mill man can erect and operate it.

This furnace having the full or partial brick lined cylinder, embraces the devices covered by the patent to John Howell, as well as the original devices covered by the White patents. It has been erected and operated successfully at the following mines in California, Nevada, Arizona and Montana, viz: Camanche, Jefferson, Leopard, Utah, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry, Independence, Endowment and Alice.

At least ten of them are now in active and successful operation, in some cases reducing ores of the most refractory character.

These facts are a sufficient attestation of the merits of this furnace.

The undersigned, with Mr. John Howell, are the sole owners of the Howell patent, and they have perfected arrangements with him, and also with Mr. J. M. Thompson, who is owner of an interest in the White patents, and as such is possessed of as full and perfect rights and powers under the same as the patentee himself, by which they have acquired the exclusive right to manufacture these furnaces for the Pacific States and Territories. We hereby **caution** all parties against purchasing the same from any others but ourselves, or the said Howell or Thompson, as we shall prosecute all parties infringing upon the same. For particulars, price and terms, address

Mining & Scientific Press Patent Agency.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system and intimate acquaintance with the subjects of inventions in our new community. All worthy inventions patented through our Agency will have the benefit of a description or an illustration and explanation in the MINING AND SCIENTIFIC PRESS or the PACIFIC RURAL PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. The files of cases and official records in our office, our patent law and scientific library (already the largest west of the Mississippi), are constantly increasing. These facilities, with the accumulation of information of special importance to our home inventors, by the experience of its proprietors in an extensive and long continued personal practice, gives them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. We can give the best and most reliable advice as to the patentability of new inventions. Advice and Circulars Free. Our prices are as low as any first-class agencies in the Eastern States.

DEWEY & CO.,
Patent Solicitors,

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

APPRECIATION ABROAD.—We copy the following rom the *Mining and Monetary Gazette*, of London, England: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of *The Gazette*, the full text of the 'United States Mining Laws and Instructions, by the Commissioner of General Land Office, taken from our talented contemporary, THE MINING AND SCIENTIFIC PRESS, of San Francisco. The documents have now been issued in a handsomely bound volume by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very useful to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. Published by Warren Holt, 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, AUGUST 10, 1878.

VOLUME XXXVII Number 6.

The Mining Debris Trial.

[Continued from Last Week.]

G. F. Allardt, an Oakland civil engineer, had made last month observations for plaintiffs. He had examined Bear river at various points, finding its velocity at one point great enough to carry rocks weighing from 60 to 70 ponnds, and calculating, by the evaporation method, the amount of sedimeut carried to vary from ahout 1¼ to 6 % of the weigbt and volume also. He had never seen slickens anywhere but in hydraulic mining localities. Had seen good corn on debris land.

A. T. Arrowsmith corroborated Allardt's testimony.

The prosecution having finished, the defense moved for a nonsuit on the ground that the injuries alleged in the complaint had not been proved, and that if damages did exist, the damaged parties had ample remedy at common law. The prosecution argued in reply, that this was a leading case, that the matter should be tested, and that the agricultural is the paramount interest of the land and should be protected. The defense in turn argued that the miners had a right to deposit their tailings in Bear river, that they were pursuing a lawful occupation in a lawful way, and had been doing so from the earliest history of the State. The Court, after reviewing the arguments, denied the motiou for uonsuit.

The defense then proceeded. An official map, representing the whole of Bear river valley and the watershed, also all the claims named in the complaint, was accepted as evidence. Senator Sargent gave a history of mining in Nevada county, the number of inhabitants in 1852, and since then, the amount of gold in their claim, and other points in detail. He said that hydraulic mining had been carried on ever since they owned the claims; that its stoppage would throw half the inhabitants out of employment and hankrupt the county.

E. H. Gaylord estimated the population near these mines at from 5,000 to 6,000. The miuing property, exclusive of quartz claims, assessed in Nevada county, is about $2,500,000. To stop the mines would injure the county greatly.

George F. Jacobs, a resident in the county for 27 years, and at one time an owner in the Quaker Hill claims, testified that their claim had been hydraulicked since 1857, and that, during the past 19 years, the gross yield of gold from them had been about $60,000 per annum.

J. S. Stone, a Gold Run miner, and Superintendent of the Cedar Creek mining company, testified to the universal employment of the hydraulic process in the districts in question. The Budsey Creek mine he estimated at $500,000. The company have been in possession of the same since 1871. The Cedar Creek property was worth $500,000; income during the past year ahout $50,000; not one-tenth of the material taken out yet, he thought. The quantity of gold taken from the district amounts to $40.000,000 or $50,000,000. There is much yet to he taken out. There are hetween 450 and 500 people supported by these mines. A stoppage would work great injnry.

J. B. Hunter, from San Juan ridge, familiar with the working of hydraulic mines since 1855, testified to the universality of the hydraulic process. It was, he said, the only proper and reasonahle method. They employed meu to a greater extent now than in early times, and these men had their families there, and subsisted on the working and income of the mines. He said the Blue Lead channel was 30 miles long, 30 feet wide, and 100 feet deep, and would pay ahout 30 cents per yard. Necessity regulates the working of the claims. North Bloomfield is among the most profitable mines in the county. Did not think one-tenth of the hlue lead had hecn worked out. Could not call to mind a claim that had heen ahandoned on this range, and would not pay.

V. A. Bell knew from observation that all hydraulic claims were worked on the same hasis; they must have a place to deposit their tailings in order to work their mines to advantage. He said the old bue lead was 28 to 30 miles in length, and ranged from 300 to 400 feet wide, and from 150 to 300 feet deep. The average worth of this land or lead is $150,000 to $200,000 per acre. There are prohably 150 to 200 claims located on this lead. Did not think one-tenth part of the grounnd had been worked out. He said the product of that mine last year was about $380,000, and this year they had taken out, up to the present time, $305,000. Witness said the population of Nevada county depended almost entirely on the working of tho mines. Did not think it would be worth while to keep up a county organization, if the mines stop work. There have heen large and extensive ditches constructed to bring water to these mines. Considered the sediment from these mines, where used in small quantities, a good fertilizer, and where put on land, had produced clovor, corn, and beans. The cereals had grown well there. Witness said he belonged to an association of miners, whose purpose was to contest this suit.

Abraham Neece, of Santa Rosa, brought out no new points.

George T. McLean gave no further eulightenment.

Gen. A. M. Dohbie had hcen familiar with miuing since 1849. The custom of dumping tailings in the ravines and streams was general, and was the only way thcse mines could he worked to advantage and profit. Mining districts were not all governed alike. Did not know of any law compelling miners to work in a certain way. Witness said he was interested in the North Bloomfield company. Was not a member of the organization to coutest this suit. Said the North Bloomfield company had tried drifting, hut it would not pay to work by that process; the hydraulic was the only process that would pay.

E. L. Bradley, of San Jose, formerly of Dutch Flat mining district, was interested in a claim in that district. Was at one time owner of nearly 20 claims. Sold them to an Englisb company for $480,000.

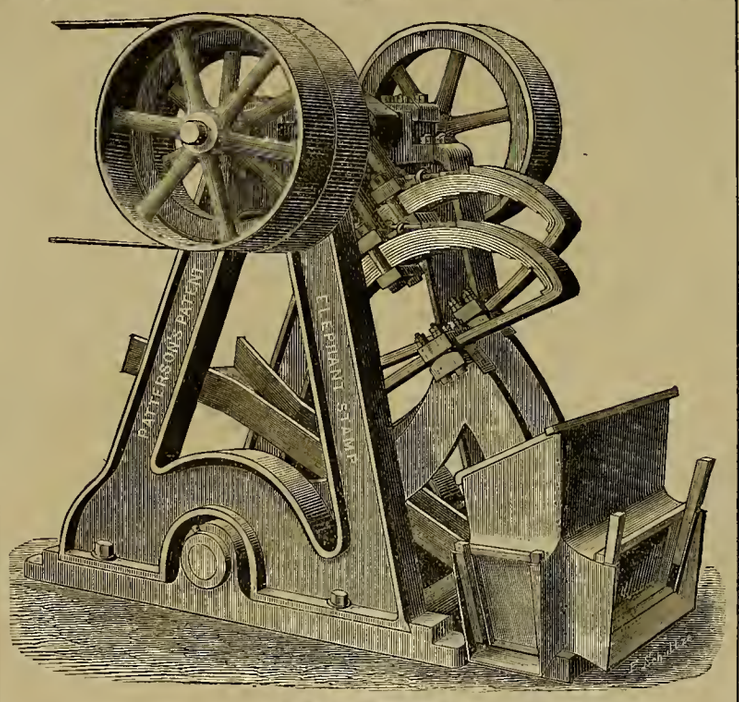
Nothing new was developed from the testimony of Andrew Laisen, O. H. Lee, S. B. Harriman and J. H. Lekamp.

Hamilton Smith had been manager of the North Bloomfield company's works for several years. He estimated the product of hydraulic mines in the State at hetween twelve and thirteen millions in 1876, and between eleven and twelve millions in 1877, and thirteen millions or more in 1878. That the mines uow being worked hy the hydraulic process would not pay to work by drifting or other process. The North Bloomfield company tried the experiment of drifting, and it cost them $2.25 per cuhic yard to get the deposit worked, while by the hydraulic system it only cost ahout five cents. He said the hydraulic mines represented about one-fifth of the taxahle property of Nevada county. Had examined the Bear River country, and the land of plaintiff. He gave a description of the sedimentary deposits and the levees built. Witness said the present levees would protect the land against ordinary floods, and they could further protect them hy increasing the size of the levee. Early mining had washed down lighter material than that coming now, and much of the old deposits would continue to wash down with each freshet. Did not believe much of the sediment or sand would pass the dams in the river hereafter. Witness said the drainage area of the Bear River valley is 350 square miles, and the rainfall ahout 54 inches. In 1861-2 there was 22,000,000 inches of water discharged by Bear river into the plains. Computed the amount of gravel and sedimentary deposit in Bear River valley at 86,000,000 cuhic yards. He was clearly of the opinion that to stop working the mines would not stop the flow of sediment. He did not consider the method of Mr. Allardt in computing the amount of solid matter in the water correct.

Prof. Wm. Ashhurner said hydraulic mines must have pressure and dumping ground to work successfully. There was no difference between the sediment in the Bear river and that in the Yuha and other similar streams. He thought sand and soft clay would make a good fertilizer. Thought most of the deposits in Bear River valley came from winter freshets and storms. He gave the amount of debris deposit in Bear River valley at 86,160,360 cuhic yards. Witness said he thought Mr. Allardt, in his estimate of solid material carried in the water, was ahout five times too much.

On cross-examination, Ashhurner gave the requirements of good soil, and his theory of the formation of the old river beds now being worked for gold.

Additional testimony will he presented in our next issue.



THE ELEPHANT STAMP.

The "Elephant Ore Stamp."

The engraving on this page represents a new ore stamping machine now heing introduced on this coast by Mr. Edmund White, and which we had the pleasure of seeing at work, on the corner of Main and Harrisou streets, in this city.

The principal novelties in the Elephant stamp are the suhstitution of hammered scrap iron levers instead of guides and rods, and the intervention of a semicircular spring between the crank and lever.

As will he seen from the engraving, the power is belted to a pulley in the crank-shaft on top of the frame work. There are two cranks on this shaft, one opposite the other. Suitahly journalled to these cranks are two heavy semicircular springs having helting across their lower ends, to which is attached the top of the stamp head. There are two stamps as shown, each heing pivoted at its rear end in a shaft. As the crank-shaft revolves, the stamps are alternately drawn up and thrown down hy the springs attached to the shaft, their forward end being supplied with shoes which strike on the dies in the usual manner.

The hlow given is a peculiar springy one, very effective in its action. The several thicknesses of leather straps connecting the ends of each spring, after the manner of the string on a how, seem to hold each stamp in such a manner that as the spring comes down a swinging kind of hlow is given to the stamp. The engraving shows how the leather springs on hoth the downward blow and return. Economy of power is claimed hy the spring storing up within itsslf the force of the recoil from the hlow of the stamp, which force is given out on the next return of the crank.

The particular advantages claimed over the present system are as follows:

"As to wearing power, the Elephant having hut two pairs of shoes and dies, the wear on the eight extra pairs which would he used in a 10-stamp mill is done away with. There are no cams, tappets or cam shaft, such constant source of wear and annoyance used, and heyond the leathers which unite the spring with the stamp head, and which would certainly not require replacing in less time than one year and may easily be replaced, the wearing parts are none."

"In the matter of power, a 10-stamp battery requires an 18 horse-power engine to drive it, while this can he run hy a seven horse-power engine. This alone is a great item, which will enable mines containing low-grade ore, which the present high cost of milling prevents being worked, to be turned into paying properties.

"As to portability, the Elephant only weighs from five to six tons, the heaviest piece not weighing over one ton. So it has a great advantage over a 10-stamp mill, the weight of which is in the neighborhood of 16 tons. On this account the Elephant is particularly adapted for new mining countries, and camps, such as Arizona, Mexico, Bodie, and Cariboo, and other places remote from the line of railroads, and where freight is necessarily high. Although the machine is comparatively light, and easily handled, yet, in case of severe handling while on the road, there are no parts which could possihly get hroken, or injured in any way, thereby securing the mine-owner against any delay in starting it up immediately on its arrival. As no wood-work is required, heyond an ordinary shed to shield the machine against the inclemencies of the weather, it requires hut little time to place the machine in working order."

As the head of the machine wears, no alteratiou in the length of the connecting rod is neccessary, the peculiar action of the spring and the flexihle connection allowing for the varying distances hetween the face of the head and the die, consequent hoth on the wear of shoes and dies, and the quality of material in the mortar. We have heen shown a numher of testimonials from Cornish firms, who have used other stamping machines, all of whom agree as to its efficency.

Mr. White, the agent, may he addressed, care of Mr. A. B. Grogan, 705 Sansome street, The machine may be seen at work at the corner of Main and Harrison streets every day from two to four, where it has heen lately examined by a numher of gentlemen connected with the mining interests.

COBALT AND NICKEL ORES.—J. S. Phillips has been appointed agent for a London firm, to huy cohalt and nickel ores. Persons having any such ores may communicate with him, through our address.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS

Iodine Manufacture on the Pacific Coast.

The following is an abstract from an article prepared by W. B. Jones, of the University of California. The subject is: "The Probability of Profitable Iodine Manufacture on the Pacific Coast." His work is based upon an analysis of a new variety of sea weed which occurs in great abundance on our coast. It may be of some interest to capitalists.

Iodine is an element, the history of which dates back but comparatively a few years. It was first discovered by M. Courtois, at Paris, in 1812. Its discovery was the result of a careful scientific investigation into the cause of the rapid corrosion of the copper pans used in the process of manufacturing saltpeter from kelp.

Sea water contains considerable quantities of iodine and is, through the agency of the sea weeds which concentrate that element, the principal source of the commercial supply of iodine.

The manufacture of iodine is at present carried on to no great extent, except in Scotland and upon the northwestern coast of France, and although not such an extensive industry as some others in the domain of "applied chemistry," yet it is quite an important one. Moreover, there is an increasing demand for the product of this industry, as the following, taken from the drug trade report of D. C. Robins, will show:

Average quantity of iodine imported per year during the three years ending June 30th, 1877, 33,698 pounds. Quantity imported during the years ending June 30th, 1876 and 1877, respectively, 24,913 pounds and 50,123 pounds, showing an increase for year ending June 30th, 1877, of 25,210 pounds. These figures take no account of the immense amount consumed by the chemical manufactories and laboratories of Europe. They give us, however, an idea of the increase in the American market.

The investigation I have conducted consists of a complete chemical analysis of the ash of a species of sea weed, which grows quite abundantly in the neighborhood of Santa Cruz. The species of this sea weed has not been definitely determined, but it is being at present botanically investigated by Prof. Farlow, of Harvard University. It seems quite certain that it is distinct from the *Laminaria digitata*, which is the source of the kelp used in European iodine manufacture. If the species is a distinct one, it will probably receive the name of *Laminaria Andersonii*, after Dr. Anderson, of Santa Cruz.

This weed grows in great abundance upon the shelving rocks at low-tide mark, and some of the plants reach a length of four to five feet, the average, however, being shorter. The analysis is therefore one of considerable interest, not only on account of the special investigation for iodine, but also because of the fact that the species is a newly discovered one, of which no complete chemical analysis has been made before.

Mr. Jones then explains some of the difficulties of the analysis and the details of the methods employed by him. The results of his analysis are as follows:

Amount of ash contained in the dried plant, 15%.

Result of qualitative and quantitative analysis of the ash:

Iron	traces
Aluminum	0.093
Calcium	9.870
Magnesium	5.320
Silica	1.210
Sodium	8.11
Potassium	15.580
Iodine	0.99534
Sulphuric acid	26.2750
Phosphoric acid	3.2400
Carbonic acid	16.67
Chloride	5.7
Bromine	traces
Total	93.06334
Loss	6.93666
Total	100.00000

Comparing the amount of iodine found in this analysis with that found in similar analyses of the dry plants of other species, we find that this species contains over twice as much iodine as any of the plants from which iodine is manufactured.

	Sarphati.	Stanford.
Fucus Vilum	0.0894	
Laminaria Digitata	0.1350	0.4788
Laminaria Saccharina	0.2300	0.1583
		Jones.
Laminaria Andersonii		0.99534

The method of iodine manufacture is quite simple, no complicated machinery or apparatus being necessary. It seems evident that if it can be profitably produced from kelp containing only 0.1350% and 0.4788%, it could certainly be manufactured with profit from a kelp containing almost 1%. Of course in deciding the question as to whether iodine can be profitably extracted from *Laminaria Andersonii* and other sea weeds growing upon our shores, we must take into consideration the increased cost of production due to a higher rate of wages.

The season for collecting the sea weeds is only of short duration in Europe; beginning in June and ending in September in Scotland, and in March and October only in France. On this coast the season would undoubtedly be of longer duration, since the winter storms which sweep away the weeds do not begin until December; and on this account the manufacture would be more continuous and therefore more profitable. Again, the market for the product and its price would have considerable influence in determining the profitability of the industry.

The market would of necessity be confined to our own country. There is at present no duty levied on the importation of crude iodine, but this fact would make no difference in the price which the product would bring, since dealers would be as willing to pay for a home product as for a foreign one, since the kelp proves so very rich in iodine, and since the profits from the extraction of the potash salts from the kelp would undoubtedly be sufficient to make up for the difference in the cost of labor between this coast and the coasts of Scotland and France. The manufacturer could afford to expel the imported product entirely from the American market.

The market value of iodine at the present time is somewhat high, it being from $4.25 to $4.75 per pound in New York, and resublimized iodine at an advance of 75 cents per pound (equivalent to the duty upon it) on these prices.

"According to Mr. Stanford's method of preparing kelp, one sample of *Laminaria digitata* produced 32 pounds of iodine per 20 cwt. of kelp." Accordingly our species, *Laminaria Andersonii*, ought to produce at least 60 pounds per ton of kelp. The ash, moreover, is very clean and free from silica, whereas in most of the other species which have been used in iodine manufacture, the silica varies from 2% to 11%. The weed grows abundantly, and during the season each cutter could easily gather at least a ton per day.

The facilities for transportation of the product are much greater than in the European localities, and this is another great factor in determining the cost of production.

Taking all these considerations, we may safely conclude that if it can be profitably manufactured in Europe from a kelp containing only one-half as much iodine, that it can be produced with equal if not greater profit on this coast, and that it might be made a source of profit to whoever should undertake the enterprise, provided of course that he possessed sufficient knowledge of the business to carry it on successfully. The occupation of cutting the weed and preparing the kelp might give employment to a considerable number of men, and thus the industry if established would prove one source, though perhaps small, of benefit to our State. W. B. JONES, Ph. B.

Benicia, Cal.

Notes on Chile.

EDITORS PRESS:—Having just arrived in this country from Chile, where I have resided for the last seven years, I have thought that a few notes from that country might be interesting to your readers. This South American Republic is well-known to be ahead of all similar States on that continent. In climate and products it closely resembles California, and I think only requires a stream of industrious and intelligent immigrants in order to have a future progress resembling that of this wonderful State. In geographical position and extent, it is of course far below California. As may be seen from the map, it is but a long narrow strip of territory from about 23° south to the Straits of Magellan, bounded on the east by the range of the Andes and on the west by the Pacific ocean. The breadth is nowhere, I think, more than 100 miles and as a great part of this width is taken up with mountainous land, the area of the plains is rather limited. The general formation of the country is that of a central valley, lying between a coast range and the main chain of the Andes. This valley, from the province of Aconcagua down to Concepcion, is very fertile, and resembles in many respects the valleys of the San Joaquin and Sacramento rivers. This is the grain-growing district of Chile, which in the beginning used to feed the California diggers. The northern provinces of Chile, from Coquimbo to Atacama, are altogether mining districts, if we except some few patches of irrigated land on the valleys of the rivers near Coquimbo and Copiapo. These are almost rainless districts, and are, consequently, dry and sterile, though they have not always been so, as is evident by the dried-up river beds and water-worn stones. And in those rare years when a shower or two of rain falls, the plant life springs up from seeds lying dormant amongst the stones, and the "desert blossoms as the rose." I am unable to say the causes or time of this change of climate, but it must have been in remote antiquity, as no historical record alludes to it. Barren as are these provinces, they are a great source of interest to the miner and revenue to the country. Here are found those rich mines of copper, which have for many years been the chief supply of the world. Here also are some rich silver mines. The chief silver mines, however, in this quarter, are those of Caracoles, in the desert of Atacama. This desert was considered so valueless that scarcely any trouble was taken by the neighboring governments of Chile and Bolivia to determine where the boundary of their respective territories lay. So that when the discovery of the rich silver mines of Caracoles first startled the world, it was a question as to which country they belonged. I believe that it has since been settled in favor of Bolivia. Mejillones-de-Bolivia is another similar case. Here is a vast field of guano, which is laid claim to by both nations; but the amicable agreement has been come to by them to divide the revenues equally. This is one of the best harbors on the west coast. The guano is brought down to the bay by a suspended wire tramway, constructed some years ago for Mr. Henry Meiggs. Last year extensive fields of nitrate were discovered on Chilean territory, which the government resolved to explore and work. They should be now in course of development. Hitherto gold has not been produced in large quantities. But that there is gold is certain. I have seen a good many specimens of gold dust and scales about the eighth of an inch or more, and once met a man with over 12 ounces.

These results have all been attained by the roughest appliances, such as the pan, and by peasants and Indians, untutored in the arts of "prospecting." So I would think that there ought to be a good show for some experienced diggers from this country. Hydraulic mining is about to be started now on a pretty large scale in the province of Valparaiso, one large company at Catapilco, all by capital collected in the United States. There were three native companies started for this purpose when I left in May last. There are legends of silver mines in the Indian territory, and I have observed that the Indians always have heavy silver ornaments of their own fabrication, so that these tales may have some foundation.

I have no wish to deceive any one with false hopes, but it is my opinion that there should be yet some great discovery of the precious metals, for the ravines and slopes of the mountains have never yet been properly surveyed nor explored to find the source of the gold dust.

The principal cities in Chile are Valparaiso, Santiago, Talca, Concepcion, Coquimbo and San Felipe. Valparaiso is a city of 150,000 inhabitants. It is the principal seaport of the country, and the commercial capital. As a port, it is rather unsafe in the winter months, being exposed to the "northers" which occur during that season, often doing much harm to the shipping. The city is built on a narrow strip of flat land at the foot of a range of high hills, and also extends for a considerable distance up the slopes. In appearance it is picturesque, only like San Francisco during the summer the hills have a dusty and dried-up look. In the principal streets the buildings, shops, tramways, and traffic all have quite a European air, and from the number of foreigners met with it is difficult to recollect that one is in South America.

Santiago, the capital, is situated in the central valley in sight of the Cordilleras. It is of about the same size and population as San Francisco. The streets are regular, and there are many buildings of great beauty and richness. The city is traversed by a long alameda or avenue of poplars, which is about 100 yards wide and serves as a promenade. Most visitors to Santiago are much surprised at finding it so much better than they anticipated in a South American town. The other cities mentioned are only large country towns, containing nothing of note.

Messrs. Clark & Co. are now engaged in getting up the capital necessary to complete their trans-Andine railway scheme to unite the systems of Chile with those of the Argentine Republic. When this work is finished, it is hoped that it will be preferred as a route from Australia to Europe.

The railroad system of Chile has advanced much during late years. Valparaiso has been connected with Santiago since about 1863 by a railroad of considerable difficulties, brought to a successful issue by the late Mr. Henry Meiggs. In 1875 the last rail connecting Santiago with Conception was laid, so that the government now owns over 500 miles of railroad. The chief engineer for these railroads is M. E. D. Poisson, a Frenchman of much talent. The contractor has been Mr. John Slater, one of the self-made men of America, who aims to be a second Henry Meiggs.

It is impossible in a brief article for me to say all that I could about Chile, but I will be glad to give any information to those who may feel interested in this country. And there is much to interest. In the scenery, history, products, present condition and prospects. I have seen a good deal, too, of the famous Araucanian Indians, the only aboriginal race who have never been conquered.

I do not think that there will ever be much commerce between California and Chile. The countries are too much alike in their products. The ruling merchants in Chile are foreigners and their descendants. There are many immigrants of all nations settled there in various occupations. It is probable that English-speaking people will always prefer to go to the United States or Australia, but there is no reason why the Germans or others who have to learn a new language should not prefer Chile. The government will treat them liberally. There are two colonies of Germans doing well. Wages and living are about the same as in California. There are no Chinese to compete with in the labor market, and hands are often scarce. At present business in Chile is depressed, owing to causes which have affected the whole world, and chiefly also to the low price of copper. But I would judge that the remedy for this state would be a flow of productive immigrants.

To judge by what I see here in California as the progress of 30 years, I have great hopes for the future of Chile, a country so similar, during the next generation of men.

JOHN SAMPSON.

Amador County.

EDITORS PRESS:—Jackson the county seat of Amador county, is prettily situated at the junction of three branches of Jackson creek—South, Middle and North forks. The buildings on the principal business street are built mainly of brick and protected from fire by iron doors and iron window shutters. The courthouse and county buildings are quite tasty specimens of architecture, and are located conspicuously upon the most elevated site in the village. There are a number of very handsome cottages with large grounds, ornamented by great varieties of shade trees, fruit trees and flowers, which beautify and make home attractive. There is a large quantity of fruit raised in the town and vicinity, the surplus of which is purchased and dried for market by an incorporated company who have here a large Alden fruit drying establishment. There are two weekly papers published here—the *Dispatch* and the *Ledger*, a number of general stores, drug stores, livery stables, saloons, hotels, also a good public school, and churches enough to supply the demands of a population of about 1,200. The altitude of the courthouse is about 1,200 feet above tide water.

Sutter Creek.

This town is situated on the stream of the same name, four miles distant from Jackson, in a northerly direction, and 12 miles from the terminus of the Amador railroad at Ione City. This is the largest town in the county, and by reason of its proximity to several very large gold quartz mines, it is the most lively business place in the county. The mines nearest the village are, first, the Amador Con. mine and mill, which employs a great many men. Next the Lincoln gold quartz mine and mill, which also has quite a long pay-roll; also the Mahoney, now shut down, owing to some little "unpleasantness" among the owners, which it is hoped will soon be adjusted, which gives employment to about 100 men. The Oneida and Kennedy mines are close, each with a large number of employes, who draw their supplies from Sutter Creek; also the Amador Canal company's saw mill and lumber yards 1½ miles from Sutter Creek, require quite a number of laborers. There are two chloridizing establishments for the reduction of gold-bearing sulphurets, two very respectable foundries, a hardware store, a drug store, two hotels, a number of dry goods, grocery, furniture, clothing, jewelry and variety stores; also a good supply of tradesmen and mechanics' shops, saloons and cigar stalls in excess of demand, two churches, a public school of 425 children, Masonic, Odd Fellows and Temperance lodges, doctors and dentists and ministers plenty, and all the other concomitants and accessories of a high state of civilization deemed necessary to the comfort and convenience of a population of 1,500 to 1,800 people, but no Chinamen.

There are many fine residences beautified and ornamented by trees and flowers in great profusion. Fruits are grown in great abundance, even the orange, which we saw in full bearing. The town is well supplied with water for household, irrigating, milling and manufacturing purposes, as well as a protection against fire. The reservoir is located on the hill east of the town, at an elevation of between 300 and 400 feet above the main street. The supply is obtained from the Amador canal, the source of which is the headwaters of the Mokelumne river.

A pleasant drive of two miles eastward from Sutter Creek, over a good road, sandwiched by fields of ripening wheat and barley, fields of new-mown hay, sending its fragrance to greet and cheer the traveler, fields of blooming alfalfa, orchards, vineyards and home-inviting farm houses, brings us to the village of

Amador City.

This town is situated on Amador creek, has a population of about 1,000, a public school with 250 children on the roll, one hotel, five general stores, one livery stable, a public hall, one church, shops, saloons, etc. The town wears a thriving, prosperous look. It is most noted, however, by its celebrated mines, of which the Keystone is the principal. This mine has turned out about $40,000 per month for the last 12 years, and gives no indication of ever letting up. They work about 100 men in the mine, the majority of whom have families and live in cottages adjacent to the works. The Original Amador mine, the Bunker Hill mine, the Gover mine, the North Gover mine, the Talisman mine, are all valuable gold mines, giving employment to a good many laborers, residents of Amador City.

The next place on the road traveling east, and about two miles from Amador City, is the village of

Drytown,

Situated on Dry creek, eight miles from Jack-

(Continued on page 86.)

MECHANICAL PROGRESS.

Narrow-Gauge Railways.

The Narrow-Gange Couvention held July 17th in Cincinnati was apparently a success, there being 200 in attendance. The proceedings of the convention may be summarized by presenting the resolutions which were adopted, for they embody the narrow-gauge idea as it is now put forth by those who uphold it. The following resolutions were adopted after careful discussion:

WHEREAS, The question of transportation has grown to such magnitude in this country that it demands the serious attention and earnest efforts of every economist to examine and ascertain the cheapest and most desirable method of conveying the products and the merchandise of the country to the various marts of the world; therefore be it

Resolved, That on account of the cheaper cost of construction, lighter operating expenses, and smaller interest account, the narrow (or three feet) gauge is the factor that will finally solve the problem, and bring the country that which it so much needs—cheap transportation.

Resolved, That the practical working of the narrow-gauge railways in America during the past six years has demonstrated, beyond a reasonable doubt, the feasibility of the gauge of three feet, proving as it has the following facts:

1. That a good road may be constructed at a cost and equipped on this gauge not in excess of two-thirds (all things being equal) of the sum necessary to construct the standard gauge. 2. That when constructed it can be operated for a sum less than two-thirds of the sum necessary to operate the standard gauge doing the same amount of business. 3. That its capacity is ample to meet all requirement. 4. That is is equally as safe as the standard gauge. 5. That the capital invested therein has proved more remunerative than like investments made in standard gauge roads under similar conditions. 6. That when built they have given satisfaction to their patrons equal to that of the standard gauge.

Resolved, That the real advantages of the narrow-gauge roads cannot be fully compared with the standard gauge roads until they can be able to reach, by extensions or connections, general distributing depots, until which time their advantages cannot be fully realized by the public.

Resolved, That the narrow-gauge road should no longer be looked upon as an auxiliary road merely because it is constructed on the three-feet gauge.

Resolved, That a narrow-gauge road may be built at the present prices of labor and material, from the Mississippi or Missouri rivers to the seaboard, capitalizing upon the basis of actual cost, and profitably compete with the water routes for the transportation of freight.

Resolved, That inasmuch as very few of the narrow-gauge railways in America have an indebtedness exceeding one-half their actual cost, and that many are projected when the companies have already secured available stock subscriptions equal to such proportion of the estimated cost, we invite the attention of capitalists to the bonds of these roads as a matter of investment, and to carefully consider the security offered, the liability of the companies, and their ability as an earning power, and that they carefully contrast the same with the standard gauge roads now in operation.

Resolved, That inasmuch as serious mistakes have heretofore been made in the location of lines possessing moment, great care should be exercised in the selection of new lines, and only those should be constructed as may be actually needed, and capable of securing a business commensurate with their cost, and that one of the best evidences whether a certain line is needed or not is the co-operation of the people along such line, and unless such co-operation equals at least one-half the estimated cost thereof, this convention would advise great moderation in the deliberations of any company before entering upon such construction.

Resolved, That the narrow-gauge railroad is the road for the people, that its cost comes within their reach, and it offers to them a transportation facility superior to that offered by any other means.

AMERICAN STREET CARS.—An expert writer says: "The English horse car weighs one-fourth more than the American car, and ultimately gives way in the joints, while those made in this country are light and strong, on the same principle that an American made carriage, though lighter, can stand more wear than an English carriage, which is altogether too heavy and apt to break, owing to its weight. The idea of making anything light, neat and yet strong, is characteristically American, and the same principle holds good in the manufacture of horse cars, and they appreciate it. There are car shops in Europe, and large ones, too, at Birkenhead, Brussels and Hamburg, and they have begun to make them in Paris, as the duty on cars imported into France is very heavy; but in Germany it is only six per cent., and everywhere the American horse car is preferred. Nothing made of wood and iron requires so much care and labor as these very cars, and I think that in their manufacture this country has really reached perfection."

Grasping and Carrying the File.

In their new work entitled "Hints on Filing" the Nicholson File Company, of Providence, Rhode Island, make the following points: In using the larger files, intended to be operated by both hands, the handle should be grasped in such a manner that its end will fit into, and bring up against, the fleshy part of the palm, below the joint of the little finger, with the thumb lying along the top of the handle, in the direction of its length; the ends of the fingers pointing upwards, or nearly in the direction of the operator's face.

The point of the file should be grasped by the thumb and first two fingers, the hand being so held as will bring the thumb, as its ball presses upon the top of the file, in a line with the handle, when heavy strokes are required. When a light stroke is wanted, and the pressure demanded becomes less, the thumb and fingers may change their direction, until the thumb lies at a right angle, or nearly so, with the length of the file; the positions changing more or less, as may be needed to increase the downward pressure.

In holding the file with one hand, as is often necessary in filing light work, pins, etc., the handles should be grasped as already described, with the exception that the hand should be turned a quarter turn, bringing the forefinger on top, and lying along the handle nearly in the direction of its length. In this position, the freest action of the hand and wrist may be had upon light work. Amateurs will find that by following these directions, the movements of the file will be simplified, and made somewhat easier than if grasped at random and without consideration.

The most natural movement of the hands and arms in filing, is to carry the file in circular lines, the several joints of the limbs being the centers of motion; this movement of a convex file would apparently give a concavity to the work, the real tendency, however, especially on narrow work, is the reverse (owing to the work acting as a fulcrum, over which the file moves with more or less of a rocking motion), giving an actual convexity to its surface, except when in the hands of a skillful operator. The real aim, therefore, should be, to cause the file to depart only so much from a true right line, as will be necessary to feel that each inch of its stroke is brought into exact contact with the desired portion of the work.

The movements here referred to, have reference to those in which both hands are used upon flat work, requiring nicety and trueness of finish, and the difficulties to be overcome in producing even a comparatively true flat surface with a file, require much practice on the part of the operator. In point of economy, the pressure on the file should be relieved during the back stroke; this will be apparent to any one who will examine the formation of the points of the teeth, when it will be seen that the file can only cut during ordinary or advancing stroke, and that equal pressure during the back stroke must be very damaging to the points of the teeth.

A SOUTH AUSTRALIAN COMBINED REAPER AND THRESHER.—Recently we gave an account of a California machine of this kind. In reports of the Paris exposition we read as follows: "James Garden Ramsay, M. P., of South Australia, exhibits a working model of a Ridley's reaping machine with improvements. This machine reaps and thrashes simultaneously. The power is traction, and during its progress through a field of ripe wheat, oats, or barley, strips the ears and so far thrashes the corn that it only requires to be winnowed before being ready for bagging. Thousands of these reapers are in use in South Australia; this machine, with one man and three horses, reaps and thrashes ordinarily 10 acres a day." It appears that this machine only works one-quarter as fast as the California Centennial Harvester, and, we would infer, it has no fanning mill attached, or else they clean grain very thoroughly by double fanning in South Australia.

GOVERNMENT HAY PRESSING IN ENGLAND.—The English government does not appear to be satisfied with the density obtained by ordinary hay presses. We read that the plant of hay-pressing machinery which has been in course of erection for some time past in the Royal Dockyard at Woolwich, was officially tested on the 20th ult., and it was found that, with the aid of this machinery, which is worked by hydraulic power, three ordinary trusses of hay can readily be compressed into a somewhat smaller bulk than that of one single truss in the space of three-quarters of a minute. The pressure applied amounted to no less than two tons on the square inch, and so powerful is the plant that as many as six trusses can be pressed into the compass of one, and the machinery is capable of turning out 300 tons of compressed hay per week, or double that amount if working day and night.

RAIL EXPANSION BY HEAT.—An English exchange says that excessive heat, 120° in the sun at Wigan, had a singular effect on the railway metals between Wigan and Manchester, on the London and North-Western line, near Platt Bridge station. The up-line to Manchester was found on that afternoon bulging for eight lengths in the shape of an S at one point, the metals and sleepers having been bodily moved nearly two feet. The rails appear to have been set too tightly, and on the heat expanding them they have been twisted off the original course.

SCIENTIFIC PROGRESS.

Notes on the Solar Eclipse.

The observations on the recent solar eclipse were generally quite satisfactory and will contribute much to our knowledge of the bodies involved. The telegraph has caught the gossip of the observers and a few points may be noted in advance of the finished reports which will be handed in ere long.

Prof. Young reported that he discovered no ultra red or ultra violet lines, but that at the moment of totality all the Frauenhofer lines were beautifully reversed. This was the most important result of his observation, and confirms the observations made in Siam. Both the H lines were also reversed. Very bright lines were seen near large B, which confirms Prof. Pogsou's observations. He also saw the bright lines F and 1,474.

Prof. Colbert reports that his observations tend to show that the moon's path in the heavens lay a little farther to the southward than indicated by the lunar tables, or else that the estimate of the moon's diameter is too large—perhaps both.

The measures made by Mr. Easterday indicated that the corona extended out on an average about 26 minutes of an arc, corresponding to a distance of fully 700,000 miles, all around the sun. It was strongly striated, and in the direction of the ecliptic the rays were nearly straight, while above and below that line they were markedly spiral in their character, and some of the lines at the base formed an angle of not less than 30° with a prolongation of the sun's rays.

The chromosphere was distinctly seen by Prof. Hough, indicating a thickness of some 2,000 miles. The protuberances were much less prominent than at most of the recent eclipses. Two rather pale ones were seen on the western side of the moon.

Mr. Thomas also saw line 1,474, but did not discover any new lines.

Prof. Watson, of Ann Arbor, and Mr. Norman Lockyer have returned from Separation. Prof. Watson discovered an intra-Mercurial planet of the size of a four-and-a-half magnitude star, about two and a half degrees southwest of the sun. Mr. Lockyer says this eclipse was totally different (the corona being 10 times brighter this time) from the one in 1871, showing a greater variation of the brightness of the corona between the maximum and minimum period of sunspots. He obtained a faint photograph of the continuous spectrum of the sun, and saw no traces of lines or rings through Mr. Rutherford's grading. The structure of the corona was well observed by him, but no trace of an exterior ring was seen, and the corona vanished instantly, while in 1871 it remained visible for several minutes after totality. Only one faint protuberance was observed by Mr. Lockyer. He is greatly surprised at the difference of eclipses occurring in different sunspot periods, and at the intimate relation of the brightness of the corona to sunspots.

Sun Engraving.

The forthcoming number of Petermann's *Mittheilungen* contains a highly interesting paper entitled "The Sun in the Service of Geography," in which the advantages of the process of heliogravure or sun-engraving upon copper, as practiced by the Austrian Military Geographical Institute, are dwelt upon. The maps of the new Austrian Ordnance map are carefully drawn on paper, on a scale of 1: 60,000. They are then reduced photographically to a scale of 1: 75,000, transferred upon copper, touched up, and printed. In this manner each sheet of the map can be produced in nine months, while the same amount of work engraved in the usual manner requires nearly 46 months for its completion. The whole of the Austrian Staff map, consisting of 715 sheets, will thus be completed in 10, 11, or 12 years. No less than 271 have been published since 1874. The advantages of this process, as regards cost and rapidity of publication, are evident, and they fully compensate for any slight inferiority in the appearance of the work. An engraver, says the *Athenæum*, to whom we showed one of the maps produced in this manner, firmly believed that it had been engraved upon copper. If the Ordnance Survey Office were to avail itself of this process, the 1-inch map of the United Kingdom, for which we shall have to wait, under present arrangements, for years, might be completed very speedily. The Ordnance survey of Palestine, at all events, might be produced in this manner at comparatively little expense, and in a very superior manner, as an examination of a specimen map in the *Mittheilungen* will show. We ought to mention that a similar process, invented by Colonel Avet, has been in use for several years past, in the office of the Italian General Staff.

PROF. HAYDEN'S LAURELS.—The Royal Academy of Sciences at Rome has elected as a foreign member of that institution, Prof. F. V. Hayden, United States geologist, who has for several years had charge of the geological surveys of the Territories. He is already a member of 33 scientific associations.

The Hughes Microphone.

We notice by English exchanges that Professor Hughes is lecturing upon this sound-swelling apparatus. Among other things he said: The problem of the microphone being solved, it required only to observe the general considerations to produce an endless variety of microphone, each having a special range for resistance. The tramp of a fly or the cries of insects required little range, but great sensitiveness. For a man's voice the surfaces were under a far greater pressure than for the movements of insects. As yet he had found no such insulator for sound as gutta-percha was for electricity. Caoutchouc seemed the best, but he had never been able by its use to prevent the microphone from reporting all it had heard. The question of insulation had now become one of necessity. If they could insulate it so as to direct its powers on a single object they would be able to investigate the object undisturbed by the pandemonium of sounds which at present the microphone revealed where they thought was perfect silence. However simple the microphone might appear to be at the first glance, it had taken him many months to bring it to its present state. He and Dr. Richardson had been experimenting on lung and heart diseases, and although the application by Sir Henry Thompson was more successful, he did not doubt their ultimate success. There was also hope that deafness might be relieved, and there was hardly a science which would not be benefited where acoustics had some direct or indirect relation. Throughout the whole of his investigations he had used Professor Bell's wonderful sensitive telephone instrument as a receiver.

ANOTHER BENNETT ARCTIC EXPEDITION.—From a communication recently received at the Navy Department, it appears that James Gordon Bennett contemplates a double expedition to the North Pole. He has been in consultation with Petermann, the great German geographer, and other Arctic experts abroad, and now proposes his well-known yacht *Dauntless* for an additional Arctic expedition, putting in her an auxiliary engine and screw and otherwise making her complete for an expedition by way of Spitzbergen. The *Jeannette* is on her way to San Francisco, and will pass through Behring's straits early next year. Benuett will spend not less than $120,000 on the *Jeannette* expedition. He wishes the Navy Department to furnish for the *Dauntless* the crew, officers and provisions necessary for her voyage, he making her otherwise ready. He is persuaded that two vessels going in different directions, but by the two ways which are admitted to be the best and only ones which promise an early success, can more than double the chances of reaching the pole.

ELECTRIC AND SUBMARINE LIGHTING.—M. Reznier has communicated to the French Academy of Sciences a description of a new electric lamp, drawing its light from incandescent poles and acting in free air. A thin rod of carbon, pressed laterally by an elastic contact and pushed in the direction of its axis against a fixed contact, becomes incandescent and burns when traversed by a pretty strong current. As the end of the rod is consumed the pressure urges it forward through the elastic slides to the point of fixed contact, where the combustion takes place. In order to facilitate the work of divers by supplying them with a submarine lamp, Barnet and Foster compress oxygen to 30 atmospheres in an iron cylindrical reservoir, from which the combustion of an alcohol lamp is sustained. The escape of the gases generated is provided for.

ILLINOIS COAL.—Mr. William D. Rudy, of the Illinois Industrial University at Champaign, has just published a very interesting pamphlet on the coals of Illinois. In the introduction, Mr. Rudy says: The coal area of the State of Illinois may be safely estimated, in round numbers, at 35,000 square miles, an area three times as large as that of Pennsylvania or Ohio, and constituting one-fifth of the productive coal fields of the United States, not including what are termed the lignite basins of the Western Territories. The coal measures of Illinois attain an aggregate thickness of 1,400 feet, and may be divided into upper and lower measures, the latter of which, as a rule, contain the better coal.

GADALINITE.—The *Engineer* says that M. Soret, in examining the spectrum of the mineral gadalinite, has observed, in the ultra violet, lines which belong to the spectrum of no hitherto known metal. He therefore suspects that they indicate the existence of a new metal. MM. Marignæ and Delafontaine had some time since suspected that gadalinite contained a new metal, and M. Soret's observation confirms their view.

A NEW ALKALOID.—According to the *Chemical News*, M. Tenrot has discovered a new alkaloid in the bark of the pomegranate tree. It is volatile and powerfully basic, forming well-defined salts. It precipitates the chlorides of palladium and gold, but not that of platinum. It gives a white precipitate with the salts of lead, mercury, zinc and silver. The new body is named (in honor of M. Pelletier, presumably) pelletierin.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

Centennial.—*Ledger*, August 3: There is not a location on the line of the mother-lode in this county the prospects of which ars of a more flattering charactsr, than the Ceutennial, situated on Dry creek, two miles south of Plymouth. The ledge is 15 feet in width, the quartz heing of that dark-streaked, rihbon character so much prized hy miners. It carries large quantities of snlphurets, and occasionally free gold is visihle. The company are anxious to get a mill upon the property as speedily as possihle, and steps have already heen taken to that end. The old Philadelphia mill of 20-stamp, located near the forks of the Consumnes, has heen purchased hy the company. Men ars now engaged in tearing it down and moving it to the Centeunial ground.

Fort Ann.—This quartz mine is located four miles northeast of Volcano, and is owned by Epling & Carr. The owners are so encouraged over the prospects, that they are now putting up a mill on the property. A dozen men are husy excavating on the mill-site and digging a ditch to convey the water. There is a pile of rich-looking ore on the dump, ready for crushing.

Drytown Items.—The Peunsylvauia cleaned up on Sunday last. A run of 11 days yielded ahout $3,000. Tbe Phenix is running successfully. Some little mining is heing done on the Consumnes river, tbougb tbe beat has heen so oppressive, of late, that many a sturdy miner has heen ohliged to throw up the sponge and quit.

CALAVERAS.

San Joaquin.—*Chronicle*, Aug. 3: The San Joaquin mine at Mosquito is being vigorously worked under the immediate supervision of its owner, J. J. Holmes, Esq. The ledge is showing remarkably well.

Silicate of Magnesia.—At his bydraulic, near the French Hospital, Mr. W. W. Cook has uncovered a bed of pure silicate of magnesia. It will require an analysis to determine whether it is steatite or meerschaum. It may possibly be chrysolite.

Banner Mine.—Active preparatious are being made to take tbe water out of tbe Banuer mine at Mosquito, preparatory to resuming operations.

LOS ANGELES.

Black Star.—*Republican*, Aug. 1: The fact is at last estahlished, that the people of Los Angeles county are not to he disappointed in tbe Black Star coal mine company. The company is, at present, taking out 10 tons per day, and, in a short time, can take out 100 tons daily. Teams are already hauling from the mine to Anaheim, filling largo contracts there. The company is prepared to snpply coal at Anaheim, and the southern end of tbe county, at the low rate of $8. Tcamsters offer to contract now for $6 per ton, delivered in the city of Los Angeles, but the company expects to contract for $4.50 per ton. The coal mine is near the silver mines, and smelting works are talked of at the Black Star mine.

MONO.

Various Mines.—*Standard*, July 31: The Bodie has opened up a rich body of ore, and the yield at Syndicate mill, from ore of tbis mine, from Friday morning to Tnesday morning, was 1,209 pounds of amalgam. This run, in a 20-stamp mill, was probably never excelled on this coast. The Standard is yielding the nsual amount of high-grade ore. The stopes in this mine were never in better condition, and their own mill was not only kept running, but the Syndicate was brought into requisition to help crush their ore. The Sigourney is making an excellent showing, for the amount of work done ou the ledge, aud is so well defined, that any one at all acquainted with miniug, can trace it right along from the point at which it was struck, 46 feet from the face of the cut. The ore runs from $30 to $300 per ton. The wbip at the Tioga seems to he a success heyond all expectation, and the numher of tons hoisted daily is perfectly satisfactory. The whistle at the hoisting works of the Spauldiug, ecboed, for the first time, througb the canyon, Monday, aud this is a signal for operations being vigorously pushed in and around their mine. The Bechtel ore is being shipped to their mill, which started up Monday morning, and thus one more mill is added to those in active operation. The Miners' mill runs steadily on Red Cloud ore, and the returns are fully up to the anticipations of all. The Red Cloud has been making additions to its machinery, and is uow using botb compartments of its shaft.

NEVADA.

Various Mines.—*Transcript*, Aug. 1: The new stamps at the Idaho will he started up next Monday. The crushing capacity of the mill will then he 135 tons per day. The mill of the Oriental mine, located near Forest City, is now in full hlast, and tbe indications are promising. The first clean-up will he made about tbe 3d of August.

Watt Blue Gravel.—Grass Valley *Union*, Aug. 2: Letter of the 27th says: The east drift is in 448 fest from shaft; gravel looks favorable. North drift is in from east drift 96 feet. No change. Machinery is all working well.

A new mining operation is soon to be started on New York hill hy a San Francisco company.

The New Yoik Hill company bave just made a rich clean-up—stated to he over $200 per load.

Diamond Creek.—*Foothill Tidings*, Aug. 3: It is now owned hy Moore, Ellis & Co., who have heen working it for about two years, with five men. There are thres locations of 1,500 feet each, one of them having heen worked hy a former company for over three years. There are at present two tunnels run into the mountain from the Diamond creek side, the lower heing 950 and the upper one over 600 feet in length. Tbe ledge, which is developed all along the entire distance of these tunuels, varies from two to six feet in thickness. The uew owners have heen cleaning out the refuse rock in the old tunnel for some time, and it averaged $6 per ton. They have commenced sinking on two chutes in the lower tunnel, and have already taken out 25 or 30 tons of quartz, that will probably yield not less than $30 per ton. There are 150 tons of rock already on the dump, and an eight-stamp steam mill in constant operation.

The Milton mining compauy's mine, at Frencb Corral, is paying bandsomely; so is their mine at Sweetland.

Rocky Bar.—A recent clean-up of a milling of rock from this mine, turned out a gold brick valued at over $5,000.

Deadwood.—The new hoisting works at this mine, to he run hy water-power, are nearly completed. Last month this mine paid a nice profit to the lessees, and the rock last taken out paid $62 per ton; so a dividend above the expense of new machinery will he paid this montb.

San Juan.—A new mining project has lately been started, wbicb will add vastly to the support of San Juan, as well as tbe townsbip and county. A company has been organized for the purpose of miuing on "Lone Ridge," so-called, near San Juan, aud are now arranging to get water on to said ridge. For this purpose they have contracted, or are contracting for, the purchase of 4,600 feet of iron pipe, which they will utilize for the purpose indicated.

INYO.

Swansea.—*Independent*, July 27: Near tbe Swansea furnace, and but a mile or two south and east of tbe first lead mine ever opened and worked on the Pacific coast, a new ledge of argentiferous galena has been struck. It exteuds the length of three claims of 1,500 feet eacb, and at the several openings ore has heeu uncovered assaying 87½ ounces per ton in silver and 50% lead. The owners are James Hanger, Mark Hand, Tbomas Ryan and Arnold Cordes. The ledge is easily accessible by tbe old Swansea wood road.

San Ygnacio.—Tbe large and very rich deposit of silver ore has led downward to a very regular and strong ledge, showing heavy hodies of rich metal on all sides. Some 13 tons now at Swansea assay at tbe rate of $289 per ton. We are informed that the owners refuse to bond the mine for 60 days at the price of $100,000, preferring to either take cash in band or keep it. There are 200 tons of $250 ore on the dump, and 1,000 tons in sight in the mine, as per careful estimates.

Benton.—Last week the Indian Queeu mill shipped four bars of bullion, the first for the present season. Tbe miue has pleuty of high grade ore in sight for a six montb's run.

Kearsarge.—It is boped that in about two months the present tunnel will strike the Kearsarge ledge about 300 feet from the surface. Enough ore will be uncovered hy this tunnel to give the mill a steady supply for a long and profitahle run, and, at the same time, make it a comparatively easy matter for the company to determine what next to do—whether to suspend in toto, or hegin a new tunnel bundreds of feet lower down to open tbis mine in true miner style. It is comparatively a small matter to tap this mine full 500 feet helow the point to be reached by the present tunnel.

Beveridge District. — Messrs. Hunter, Hughes, Porter and Brittain, the owners of the main locations of the new Beveridge gold fields, are putting up a couple of arastras for the working of their ores, the motive power of which is to he steam.

Defiance.—Coso *News*, August 3: Timbers and supplies have heen hauled to tbe mine. In two or three weeks we hope to hear the whistle of the Defiance's furnaces.

SAN LUIS OBISPO.

Chrome Iron.—*Tribune*, July 27: Among tbe many resources of California that have not yet heen brought into prominence, especially in this county, is that of cbrome iron. Witbin the past five or six months many of our citizens have heen prospecting through the mountains in search of minerals of various kinds, and some inquiry baving been made as to the intrinsic value of tbis article, they were led to make investments, wbicb, however, up to tbe present time, bave not heen remunerative. We think that credit should be given to Messrs. Goldtree Bros., S. A. Pollard, R. R. Harris, E. L. Reed, Louis Flores, and others, for tbe determination tbey bave evinced to prove tbe worth of this new, and almost leading export of our county. These gentlsmen have given both time and money in developing their various mines, have kept in constant employment from fifty to one hundred laborers, and had about ten wagons continually on the road. Since April 1st they have delivered about 2,000 tons of ore at the depot, and bave on hand about 2,000 tons, lying at the mines, ready for shipment. Unfortunately, so far, tbere is but one firm in San Francisco that buys and ships tbe article to the East, and therehy has a monopoly, to the detriment of ths shippers. Cannot our metropolitan press, through its columns and their eastern exchanges, call the attention of the public to this source of wealth, and thereby assist not only the producer of this county, hut also the eastern manufacturers who may need the article, by bringing to their notice from what source they can ohtain an unlimited supply of the raw material. There heing so much idle capital in San Francisco, there is not, in our opiuion, a safer veuture for some of our merchants to enter into than the husiness of huying and shipping this ore to the eastern and European manufacturing centers, where, as we understand, there is an unlimited demand for the same.

SHASTA.

Copper City.—Reading *Independent*, Aug. 1: Reports from the mill of the Extra company are very encouraging. Mr. William Thompson showed us a nice silver button, the first small assay taken out of the rock they are now crushing. The Superintendent is confident that the process they are using to separate the silver from the hase metals is a complete success; which, if correct, will insure the building of probably two more mills the present season.

SISKIYOU.

Our Mining Interests.—Yreka *Journal*, July 31: The new rich strike in the Klamath mine, at Salmon river, hids fair to ssnd into market an immense quantity of the glittering ore, and the Black Bear company have also found a new extension which pays mucb hetter than the old rock now worked. In the Scott valley districts of Oro Fino, Muggins ville, Rattlesnake, Frencb Creek, South Fork, Pinery, and other sections, the quartz mines are all prospecting good, and the surface, bydraulic and drift claims on McAdams, Cberry, Dsadwood, Paterson, Indian, and other creeks, are also producing a good supply of tbe yellow dust. All along the Klamath and on Scott river, the river claims are ahout opened, so as to take out the pay gravel from uuder the river-bed, in working old channels, in which the gold can be taken out in great quantity. At Oak Bar, Hamhurg Bar, and Scott Bar, hig strikes are constantly being made, while in the Pacific mine, at mouth of Hamburg, considerable gold is heing taken out in runniug tunnels to prepare for work; and where the company, besides working in tbe old Klamath river channel, are also huilding a tunnel to strike thc old Humbug creek channel at the junction with the Klamath. At the Empire quartz mine, on the Klamath, near Humhug, the mill will soon be at work ou a large amount of quartz, ready for crusbing. Ou Greenhorn creek, we anticipate a good clean-up from the Warren & Neshit steam mill, which has heen running for some time past. The ledge worked hy A. V. Burns, on Long gulch, also yields good quartz from a well-defined ledge, liable to last for years in affordiug good pay; while over on the North Fork of Humhng, Cornish & Co. are still busy opening their ledge by a new tunuel, with the expectation of soon heing able to get the rock down to wagon-road by au iucline track and wiro rope. In addition to the river and quartz mining, the placer claims at Hawkiusville, Humbug, Cottonwood, Littlc Humhng, and up in the Siskiyou mountain sections ou Hungry and Beaver, more gold thau usual is being taken out.

TRINITY.

Items.—*Journal*, Aug. 3: C. M. Loveridge, Superintendent, iuforms us that the final clean-up was made last week in the Ward mine on Oregon Gulch mountain; result, $4,700. This makes a little over $19,000 for the season, which is considered a very good showing. Miners in Weaver basin are fast completing the work of this season, and some of tbem are already doue cleaning-up. The season has been a favorable one for water, and all tbe claims bave paid well.

Nevada.

WASHOE DISTRICT.

Con. Virginia.—Gold Hill *News*, Aug. 7: Daily yield, 40 tons of ore. Therc is no change to report of auy of the ore stopes on the lower levels. At the C. & C. shaft the operations were somewhat delayed during tbe first part of the week hy the hreakage of the strap of a pump rod. That bas been repaired, however, and the sinking resnmed. The repairs to the Consolidated shaft are being pushed as rapidly as possible, the removal of the platforms for eight hours each day being greatly heneficial in cooling off the lower portions of the mine. A new winze (No. 3) has been started in crosscut No. 3 on the 1750 level, to connect witb crosscut No. 3 on the 1850 level.

Ophir.—Two breakages of the macbinery bave occurred to interfere with the progress of the ore developments aud prospecting on the lower levels during the week. Tbe breakage, along witb a strong drainage of hot water from the soutb drift on the 2000 level, has allowed the water to get so strong a head in the bottom of the main incline, that it was necessary to start the water tanks, the running of which, along with the steam generated, has stopped the sinking of the incline, and greatly interfered with the progress of work on the 2100 and 2000 levels. The east drift on the 2100 level is in 46 feet, tbe face in hard blasting porpbyry. East crosscut No. 2 on the 2000 level is in 95 feet, the face still in quartz and porphyry. The repairs to the pump are uow completed, and ths pumps running as usual.

Savage.—But little change during the week. The water is being held steady at a point a few feet helow the 2000 level. The starting up of the Hale & Norcross machinery will now enahle the two mines to again work together, so that it is likely that the water will soon he sufficiently lowsred to resums active work in tbe crosscuts on the 2100 level.

California.—Daily yield, 260 tons of ore. There are no new features to report of any of the ore-producing sections of the mine. The stoppage of work in the Consolidated shaft, for eight bours each day, gives the lower levels of the mine a chance to cool, and greatly assists the extraction of ore. The heat still continues great, and there still remains some 35 feet of the shaft to repair, to reach the 1400 station. Sinking the joint winze, helow the 1900 level, on the Ophir line, is going vigorously ahead. The northwest drift, on the 1650 level, has reached tbe ore stopes, which connection will greatly assist the ventilation and extraction of ore at that point.

Justice.—The south lateral drift, on the 1300 level, is steadily advancing, the face still showing spots of excellent ore. No. 4 crosscut, from this drift, is also showing stringers of rich ore. The chamher, for the hoisting engine and other machinery, at this winzs, is about completed. West crosscut No. 1, on the 1225 level, is steadily advancing, the face in favorable quartz. The main south lateral drift, on this level, is being retimbered in the most substantial manuer, the face of the drift being in soft, favorable quartz, with spots of rich ore. The water in the main incline appears to he subsiding gradually, the work for the pumps now being very light. It is probahly hsing drained by the pumps of the Alta mine.

Union Con.—The new ore discovery in the Sierra Nevada incliue, near the north line of this claim, is hringing it once more promineutly to the front, as one of the most encouraging prospecting mines on tbe lode. The width, depth, nor extent of this new deposit havo, of course, not yet been determined, hut there is no doubt that tbe ore is improving as it goes downward, and there is no doubt whatever hut the Union Con. will get a good slice of it. Auother encouraging feature is ths strong resemblance of quartz and ore to that found ou the 2000 level of the Ophir, while the fact that the 2100 level of the Sierra Nevada is equal to the 2200 level of the Ophir, gives still greater significance to this "find." The north drift, on the 1600 level, is now in 567 feet, and is advancing at tbe rate of two and a half feet per day. It is necessary to keep a portion of the men at work, retimboring this drift, tbe ground in places being quite soft. The joint east Mexican drift, on the south line, is in 508 feet, the face still in hard blasting porphyry.

Silver Hill.—Yesterday, a splendid vein of healthy ore-bearing quartz was struck hy the nortb drift, on the 800 level. This quartz is of a very compact, yet lively, nature, and promises the finding of ore of a paying character at every step of advancement made.

Overman.—The south drift from the hottom of the winze, on the 1600 level, is making rapid headway, the face also in hard blasting porphyry. Sinking the joiut winze on the Caledonia line, helow tbe 1400 level, has been suspended on account of the strong flow of water encountered.

Con. Imperial.—The west crosscut (No. 3) on the 2400 level has penetrated into some very fine quartz, mixed with porphyry to some extent. Along with this discovery came a flow of water, which created a fear tbat, witb only small donkey pumps to keep down the flow, there was danger of flooding the entire level. It was therefore deemed hest to suspend work in the drift for a few days.

Crown Point.—The north drift on the 2300 level is advancing at the very rapid rate of seven feet per day, toward the north line, running parallel with the ore veiu. The south drift on the 600 level is making good progress, notwithstanding some little delay created by tapping a small stream of water.

Gould and Curry.—The water is entirely drained from the 1900 level, and the drifts both north and south are being cleaned out and repaired.

Lady Washington.—The north drift on the 1300 level is steadily advancing, the face in lively quartz and ore. The north drift on the 1150 foot level is advancing in very heavy clay and porphyry ground. A compromise has been effected with the Benton, Boyle and Keystone mining companies, hy which the stockholders in the Lady Washington company will receive 54,000 shares of the stock of each of the new corporations of those companies, in lieu of the 60,000 shares now held hy them; the stockbolders of the Benton will receive 54,000 shares of tbe Benton Consolidated; the stockholders of the Keystone will receive the same numher, and the shareholders of the Boyle will receive 54,000 sbares of the Lady Washington Consolidated. One share of stock in the Lady Wasbington will entitle the holder to nine-tenths of a share in each of tbe new corporations.

Bullion.—Sinking the main incline is making the best of progress, the bottom almost entirely in quartz, affording good assays. The under side of the incline just cuts the foot-wall, while the entire size of the shaft is in quartz and low-grade ore. The east drift, on the 1700 level, is steadily advancing, the face in porphyry, carrying fine stringers of quartz.

Con. Dorado.—Very good work is being done, siuking the new three-compartment working shaft, and the uew hoisting works are nearly completed, and ready for active practical mining operations. Bottom of shaft in good working ground.

Sutro Tunnel.—Total lengtb of tunnel, to

date, 20,312 feet. Most excellent advancement has been made of late, owing to the vastly improved facilities given by the thorough ventilation, effected through connection with the Savage workings.

BEST & BELCHER.—The retimbering of the joint winze, on the 1950 level, is making the best of progress.

HALE & NORCROSS.—The new air machinery was started up yesterday noon, and is all running in full blast, everything working splendidly. The lower levels will soon be cooled now, so as to permit the resumption of work on the 2000 level.

JULIA CON.—The water was so nearly reduced to the 2000 level, last evening, that it was confidently expected that by this evening, or to-morrow morning at the farthest, the level would be drained.

TROJAN. The extraction of ore, and the opening up of new stopes, on the third and fourth station levels, is making good headway.

SUCCOR.—Sinking the main shaft is making the best of headway, the rock in the bottom blasting out finely, and the flow of water giving but little trouble.

ORIGINAL KEYSTONE.—The new shaft is now down 31 feet. The prospecting shaft, on the north end of the claim, is down 40 feet.

WARD.—Sinking the main shaft is making the best of progress, the bottom in good sinking ground. The rock blasts well, and the flow of water gives but little trouble. It is now down within a few feet of the 1400 level.

CROWN POINT RAVINE.—The new pump and machinery will probably be in working position by the 20th of the present month, when sinking the shaft will be resumed and the excellent ore prospects of the mine proceeded with.

EUREKA DISTRICT.

ALEXANDRIA.—*Sentinel*, July 31: The returns of the late working of the ore, sent to the Richmond company's furnaces, for reduction, from the Alexandria mine, on Prospect mountain, show: Silver, $159.15; gold, $53.13; total, $212.28. It is stated that the ore body is increasing both in quantity and richness, promising to open out into a regular honanza.

JACKSON.—There is no longer a doubt that an important development has been made on the 300 level of the Jackson mine. It occurred to the southward of the main sbaft, and is viewed as of the highest importance, as demonstrating the trend of the ore in that direction.

ACCIDENT IN THE K K.—*Sentinel*, Aug. 3: Some of the machinery, connected with the pumps, at the K K mine, broke last evening, at eight o'clock. This will cause a delay, until a new one can be cast. It is hoped that everything will be in running order hy this evening.

LATER FROM THE JACKSON.—The new ore find in the Jackson was penetrated seven feet yesterday, showing good ore all the way. There can hardly be a douht that it is a honanza of good size aud grade.

HUMBOLDT DISTRICT.

FAIRMOUNT MINE AND MILL.—*Silver State*, Aug. 3: The Fairmount mine, in Winnemucca mountain, is now being tboroughly prospected. All three of the levels are heing run into the hill, and are being connected hy winzes for the purpose of ventilation and opening stopes. The ledge improves as the drifts on it are being extended into the mountain, and looks as well as the owners could reasonahly expect. Work is heing prosecuted vigorously on the new mill, and it is expected that it will he steamed up and the hattery running within three weeks. A roasting furnace will he huilt for the purpose of treating the pulp hefore the pans are started. Ore is now heing hauled to the mill, and it is intended to have 150 or 200 tons on hand when the battery starts.

PARADISE AND MOUNT ROSE.—Governor Safford and party returned from the Paradise mines yesterday, and departed for the west last evening. They expressed themselves as being very favorably impressed with the appearance of the new mines. L. W. Greenwell and L. P. Coscia, of Rye Patch, and E. P. Torry, of Orcana, have gone to the mines, with the view, it is said, of making arrangements to huild a mill in Mount Rose district, for the purpose of doing custom work.

RED DEER.—We are informed by Hohart Luther, that the ore from the Red Deer mine, recently worked at Torrey's mill, yielded $1,125. It was worked up to 85% of its assay value by the ordinary mill process.

Utah.

PARK CITY.—Salt Lake *Tribune*, Aug. 4: In the nortb tunnel of the McHenry mine, 150 feet of following a seam has opened up a fine chamber of ore, consisting of silver, manganese, copper and chloride of silver in good quantities. This ore is now heing taken to the mouth of the tunnel, assorted and stowed away. Average assays from it will not fall less than $60 silver. The Empire company are doing little just now in prospecting tbeir respective claims. In Charcoal avenue, or the little canyon leading to the Walker & Webster mine, a couple of Salt Lakers have commenced the erection of leaching works. Good leaching ores are found in quantities in the Uintah district, and it is generally believed that money, and plenty of it, can he made hy working the ore in this manner. Five miles southwest of Park City, Mr. Burt Kimhall owns some valuahle prospects. He hrought to town, a few days since, some rich specimens, containing hromide of silver, chlorides and metallic silver, gold and copper, thus showing that we have as rich deposits southwest and west of town as we find directly south. The new shaft of the Ontario is down over 300 feet, and hut little water met with so far. Mill running steadily, all the 40 stamps crushing and regular daily shipments of bullion made.

THE National mine is looking bettor than ever before. About five tons of ore are being taken out daily, averaging 56 ounces of silver and 65 % lead. The Leonora mine is developing handsomely. Four men are at work on a two-foot vein of pure galena, which assays 40 ounces in silver and 60 % lead. The Watterman smelter has again started up after a thorough repairing.

ITEMS.—The mills at Silver Reef are nearly all undergoing repairs. The Old Telegraph leaching works are nearly completed. Eugine, pump, and hoisting works of the Oregon Con. are running nicely. The mine looks well. On July 31st, 23 tons of ore from the Triwaukee mine, Bingham, were sold at $80 per ton for the Alta sufferers. The Morgan smelter is shut down, having run out of coke.

FRISCO.—Godbe & Co. have nearly completed their new improvements on the smelter, and they will be ready to start up in a day or two. Their roaster works well, and they now convert tho finest flue dust into a matte that runs like water in the furnace. Rich lead ores containing 600 ounces of silver, are now being received by them from the Horn Silver mine. Campbell, Cullen & Co.'s furnace is running along and making lots of bullion. Harries & Tisheer's mine in West Camp, called the Belle of Frisco, is looking splendid and ore containing 80 ounces silver is being extracted. The ledge is ahout three feet wide, and only a depth of 20 feet has heen attained.

STOCKTON.—The reduction in the price of lead has injured this camp. However, attention is beiug given with encouraging results to extractiou of silver.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

JERSEY M. Co.—August 1st. Capital stock, $10,000,000. Directors—Philip H. Cramer, J. F. Place, George F. Gersel, W. T. W. Schenck and C. R. Greathouse.

FLORENTINE M. Co.—Capital stock, $500,000. Directors—B. F. Seihert, J. H. Yocum, Wm. Gilbert, D. E. Miles and A. C. Taylor.

HIGHBRIDGE S. M. Co. Directors—Stephen Roberts, W. S. Gage, George R. Williams, John F. Cassel and David Goodman. Capital stock, $10,000,000.

THE EUREKA PROCESS.—Mr. E. H. Long, of Washington district, Esmeralda county, Nev., has recently had eight and one-half tons of ore worked by Mr. Hallock, by the Eureka process, at the works at Melrose, and the results have been so satisfactory, that he has bought the right to use the process in the district, and will put up works there. The ore is rehellious, and they have not been able to do anything with it until now. Mr. Long informs us that he was ahle to get about 80% of assay value of the galena character, and with tbat of the coppery character, he got upwards of 90%. The Eureka process is that invented hy Mr. Hallock, with which experiments have heen made during the last three or four months. Mr. Hallock says he has many visitors at his works, and will he pleased to see any mining men who may desire to see bis process at work.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have heen as follows: Tyho Con., July 29th, $8,485.18; July 31st, $5,060,50; total for July, $64,492.59; Aug. 2d, $5,344.77; Star, July 29th, $3,603; total for July, $30,042; Aug. 2d, $2,742; Gold Hill, Aug. 2d, $6,319.19; Standard, Aug. 2d, $19,563.21; California, Aug. 2d, $79,968.37; total to date, $263,606.15; Con. Virginia, Aug. 2d, $58,671.56; total to date, $124,721.39; Northern Belle, July 31st, $8,428.69; Aug. 3d, $11,866.37; Bodie, July 30th, $22,595.57; Aug. 1st, $24,427.62; Aug. 2d, $16,462.64; Aug. 3d, $29,600; Hackberry, Aug. 5th, $5,000; Indian Queen, July 30th, $4,441.26; Manhattan, Aug. 6th, $12,200; Leopard, Aug. 2d, $6,400; Grand Prize, Aug. 2d, $4,925.21; McCracken, Aug. 5th, $8,548.78; Independence, Aug. 5th, $12,116.06.

MESSRS. TATUM & BOWEN, formerly of Tatum & Co., of No. 51 Fremont street, have removed to No. 3 Fremont street, corner of Market. At the new place they have sufficient room to carry their stock, which was previously stored at public warehouses. Their stock consists of Albany lubricating compound and cups, cylinder oil, and lubricating oil, Downer's mineral sperm, Hoe's chisel-tooth saws, Hoe's printing presses, etc. They have now also the agency of the Stearns' Manufacturing Company, of Erie, Pa., for their saw-mill machinery, of which about 10 car-loads for Dolbeer & Carson's new mill, up the coast, are on the way.

DURING the year ending June 30th, 1878, vessels belonging to the port of San Francisco to the value of $285,550 were lost. Lives, 82.

THE New Orleans Board of Healtb report 24 new cases, and seven deaths from yellow fever.

News in Brief.

IN Iowa, corn promises as well as last year.

THE crops of Oregon are, on the whole, good.

POTATO crops in Clear Creek county, Col., good.

THE Mayor of Jefferson, Texas, receives a yearly salary of $1.

MICHAEL REESE died on August 2d at Walleustein.

BEACONSFIELD and Salisbury were feted by the city of London on August 3d.

ON August 2d, $7,000,000 worth of the 4% bonds were sold.

ON August 2d, Capt. Webb swam 22 miles in the Thames, without rest.

IN western Iowa the yield of wheat this year will be 12 to 15 bushels per acre.

INSURRECTION in Herzegovina; Governor of Mostar assassinated.

THE highest temperature in San Francisco during July was 73°; lowest, 51°; average 57.8°.

ON August 1st a tornado swept through eastern Indiana, damaging crops, trees, and buildings.

UP to August 3d, the total number of yellow fever cases in New Orleans was 233; deaths, 60.

IT is estimated that the salmon catch on tho Columbia river, this season, will aggregate 380,000 cases.

IT is unlawful to catch salmon in the San Joaquin and Sacramento rivers before the 1st of November.

THE number of deaths in San Francisco during the year 1877-78 was 4,977 against 6,170 the previous year.

THE entire yield of wheat in Michigan this year is 30,000,000 bushels, an average of from 19 to 20 bushels per acre.

JOHN ROBINSON, near Fort Benton, Montana Territory, in nine days, took out, with a rocker, $4,000.

THE largest flour mill in the world is now heing built at Niagara Falls. Capacity, 1,200 barrels per day.

ABOUT 18 citizens of Umatilla county, Oregon, were killed and 11 wounded during the Indian raid.

A PARASITE called the "scale louse" is spreading destruction among the orchards of Santa Clara valley.

A SYNDICATE of English capitalists has been formed to open the Cariboo quartz reefs, where prospecting is progressing satisfactorily.

ON the 1st of August, Alta, Utah, was entirely destroycd by fire; loss may reach $200,000.

NINE vessels are reported lost, and six ashore in a storm on the southwestern coast of Cuba, on the night of July 30th.

THE will of Whiting Street, of Northampton, Mass., who was worth half a million dollars, leaves about $25,000 for eharitahle purposes.

MANUEL BRIN has discovered a ledge eight feet wide, averaging $17 in gold, and $20 in silver, 18 miles north of Pyramid lake, Nev.

STAGE, 18 miles from Tucson, was robbed August 3d. Express hox empty; mail sacks contained little; the passengers lost $37.

WITH a view to exteusive distrihution of the tea plant in the Southern States, 300 pounds of the seed have been lately sown at Washington.

JOHN BURNS has instituted suit against the Southern Pacific railroad to recover $51,120, damages sustained from one of the company's locomotives.

THE total length of railroads in the world at the end of 1876, was 184,002 miles. America has nearly as much as Europe. The United States have 74,095.

ON August 4th, lightning struck a Sunday school tent in Philadelphia. One scholar was instantly killed; three others were fatally injured; all were knocked down.

DURING the past year, the Experimental Department of Agriculture at Washington, distributed over 20,000 tea plants, grown in the greenhouses of the department.

DURING a severe thunderstorm, July 31st, Valk & Co.'s planing mill, at Rock Island, Iowa, was struck by lightning and burned to the ground. Loss, $25,000; only $1,000 insurance.

THE British ship *Loch Ard*, from London for Melhourne, with a eargo valued at $350,000, was lost near Cape Otway, June 1st. One passenger out of 17 was saved; also only one out of a crew of 32.

OWING to the prostrate condition of the cotton trade, Hornby & Son, the large mill-owners in the Blackhurn district, have given a fortnight's notice to their operatives that they will close their mills.

THE worst injury in the Northwest to wheat, from the excessive heat this year, has heen in northern Iowa and southern Minnesota. The yield will not be greater than 10 bushels per acre.

THERE will he as much business for the Chicago and Northwestern railroad in every article of grain, except wheat, as there was last year. The damage to the crops has been considerably over-estimated.

The Chinese Ambassador, Chun Lan Pin, and suite, together with the Consular corps, left San Francisco, August 2d, on a special car, via the Rock Island and Lake Shore railroad. On arriving at Hartford the Ambassador will leave most of bis suite and proceed direct to Washington, where he will present his credentials to the President of the United States. After visiting Washington he will start from New York for Madrid, returning to Washington in December.

NEGOTIATIONS are said to be in progress for the cession of Rhodes and Scio to France.

THE M. K. & T. R. R. sold 60,000 acres of land during the first six months of 1878.

A SERIOUS unpleasantness is rumored between the Italian and Austrian Consuls in Bosnia.

THE marble mills of Vail, Shotwell & Co., N. Y., have suspended. Liabilities, $100,000.

THE coal ledge at Willow creek, Siskiyou county, has improved at a depth of 17 feet.

A HUGE 80-stamp mill is soon to be started at Lead City, Dakota Territory, on the Homestake ores.

JAMES REID & Co., New York, have suspended. Liabilities, $200,000; assets, $100,000.

THE Graham Block at Visalia was destroyed by fire, August 3d. Loss, $7,000; insurance, $4,250.

IT is said that more miles of railroad will be built this year in Colorado than in any other State.

ON August 3d, Edison visited the San Francisco Stock Board, and noted the acoustic properties of the room.

THERE have been 120 mining locations made at Silverado, the new mining camp in Los Angeles county.

ON August 3d the Masten Bank of Kansas City suspended; also the grocery house of Bishop & Co., Cincinnati.

THE capacity of the wire mill of the Cambria Iron Works, Johnstown, is to he increased from 30 tons per day to 60 tons.

THE shipments of iron ore from the Lake Superior region up to the 10th of July amounted to 419,473 gross tons.

ON August 3d, the house of J. C. King, N. Y., was robbed of $19,000 U. S. 4% bonds, and $10,000 curreney.

NOBELING, the would-be assassin of Emperor William, is reported to have attempted suicide with a pair of scissors.

AT the Walla Walla, W. T., Land Office, since it was established in 1871, the cash receipts for lands sold, reached $155,912.27.

A NEWLY discovered mine in Frankliu couuty, Pa., is said to contain hy far the richest copper ore yet discovered in tbat State.

THE Sheffield (Eng.) *Daily Telegraph* announces that a single Sheffield firm has this season ordered 50,000 American hay rakes.

A GOOD many of the mines in the Lake Superior region are lessening their forces, owing to the depressed condition of the business.

A UNIQUE sketch of California mining life, from tbe pen of Mr. Rossiter W. Raymond, is now appearing in the New York *Christian Union*.

ON August 2d, the steam saw-mill of Boney & Co., Washington county, Oregon, was destroyed by fire, together with 150,000 feet of lumber.

O. S. DILKE, of the late firm of Townsend, Clinch & Dilke, N. Y., has gone iuto voluntary bankruptcy. Liahilities, $154,000; no assets.

THE University of Copenhagen is ahout to celehrate its fourth eenteuary. Delogates from various foreign universities are to he present on the occasion.

THE value of the coin and hullion exported from New York city during the six months ended June 22d, 1878, was $946,350.34, nearly half of which went to Liverpool.

A STATUE of M. Thiers is to he erected at St. Germain, where he died. A statue is also to he erected at Nancy, and mass is to be celebrated at Notre Dame on the anniversary of his death.

THE annual yield of Zacatecas district, Mexico, from ore averaging $45, 8,000 men and boys heing employed, is about $5,000,000. That is $65 to the man. Virginia City, Nevada, gives $10,000 to tho man.

THE American Minister to Turkey has sent the gunhoat *Dispatch* to investigate the ease of an American lady, who founded a missionary school in Thessaly, and who is said to bave heen scriously molested hy Greeks.

DR. JAMES S. MEYER, of Virginia City, Nevada, claims to have discovered the secret, by means of which tbe ancieuts were ahle to make tools and weapons of hrouze and copper of a temper superior to that of the best steel.

ON July 2d, a couple of boys found two yellow and old bars of hullion in the mouth of an old tunnel in Virginia, Nevada. They say a man stole the hars from them. The man denied it, and was locked up rather than give bail.

G. H. PALMER has discovered a hot sulphur spring seven miles west of the Panamint range, on the east slope of Saline valley. Altitude, 500 feet ahove salt beds; width, 30 feet; deptb, great; watcr very clear and intensely hot. Good, when cooled, for drinking.

GEORGE CRAWFORD, together with a "Colonel" of the same family name, attempted to precipitate a large quantity of forged Ophir stock upon the market. Detectives frustrated the plan. George bas been re-indicted hy the Grand Jury.

THE Kansas Rolling Mills, near Kansas City, have found natural gas at their works from a small shaft sunk to the depth of about 300 feet. The gas is sufficient for lighting the mill for any purpose of night work, hut the intention is to utilize it for heating purposes.

Two heavy rain storms, accompanied hy thunder and lightning, swept over Philadelphia on August 1st, doing considerahle damage to tbe exhihition huilding and goods therein. Cellars were flooded level witb the streets in many places, doing immense damage to goods stored in them. Culverts were chocked, trees blown down, and roofs demolished.

Continued from page 82.

son. This is an old mining camp, and was during the flush times of placer mining a very lively place. There is a good deal of farming and fruit growing in the neighborhood. There are no mines being worked in the immediate vicinity of the town at the present time, but about a mile distant is the Californuia Potosi, a mine that bids fair, from present developments, to become an important industry.

Plymouth.

This place is three miles northeast of the last mentioned town. Population, 650; public school, 200 pupils; three hotels, four general stores, two drug stores, two variety stores, one livery stable, blacksmiths, jewelers, butchers, three physicians, two churches, etc. The Phenix gold mine and mill, owned by Alvinza Hayward, of San Francisco, is situated in this town, which is the basis of the business-like appearance and evident prosperity of the town. The mine and mill give employment to 105 men, who live in handsome cottages in this pleasant village, their houses being surrounded with fruit and shade trees and beautified with flowers. The town is also surrounded by quite an extensive farming community who have been well rewarded for their labor, especially in the greatly increased hay crop.

Seven miles east of Plymouth, over a good ridge road and through a pleasant and thrifty farming country, brings the traveler to the old mining camp of

Fiddletown,

Or, as it is to be called in future, Oleta. This place was settled in 1850 and rapidly acquired a very large population. Dry creek, which runs through the town, and Slate creek, one and one-half miles south, and all the gulches and ravines putting into them were very rich, and the tourist—when one strays through this ancient camp—is regaled in turn by the few semi-human fossils, remnants of '49 and spring of '50, with the immense strikes, big nuggets, large fortunes and happy times realized by themselves and their associates in the distant past, when they were young and full of ambition and energy, when, too, the country was young and bright and the mines apparently inexhaustible, and to them in their thoughtlessness and improvidence gave promise of forever honoring the daily drafts upon their stores of hidden wealth, but alas, the end came, the mines were worked out, the money was soon expended, and the few old settlers who have survived the flush times do little else than bewail their seeming misfortunes, or recount their successes in the early settlement of the county. This place has been singularly fortunate in escaping the ravages of fire. Many of the old shake cabins built in the quaint style of architecture prevalent with the frontier are still standing, embowered by climbing roses and honeysuckles and shaded by forests of tall locusts, black walnuts and cottonwoods.

Volcano.

This town, settled in '49, was originally called "Soldier's Gulch," but the next year the name was changed to Volcano, which seemed more appropriate and euphonious. It is situated in a deep basin washed out by Sutter creek, though having the appearance of an old crater or bed of a lake. Powerful dynamic forces have evidently been at work here, the vicinage presenting an interesting field for the study of geology. Volcanic, diluvial, glacial and earthquake agencies have all left traces of their action in the tall hills, deep ravines and lava flows of the neighborhood. The rich alluvial soil, resulting from the attritiou of these warring forces, and the more genial influences of the atmosphere and sun, holds the gold that at first so richly rewarded the labors of the miner, and produces the abundant crops of grain and the luscious fruits that bless the farmer and the orchardist. The placer mines have been fabulously rich, it being estimated that $25,000,000 have been taken from this small basin. Mining and prospecting has been much neglected since the surface placers were exhausted, until the last year, when a little life was infused into this lethargic population by a few enterprising men, who have undertaken to develop some of the untouched mineral resources of this extraordinary locality. A tunnel is being run in to tap the basin, starting one mile below town on Sutter creek, and when completed will affect a drainage 42 feet deeper than it has heretofore been worked. This tunnel will drain several hundred acres of mining land, and undoubtedly make available a large amount of hidden treasure.

Another enterprise which promises large pay is the opening of a gravel bed on Grass Valley creek, near Volcano. This is a work requiring considerable capital, as a cut through the rim-rock had to be blasted to a great depth to get sufficient fall. This property is owned by Mr. Charles McLaughlin, of San Francisco, and the work is being managed by M. L. McLaine, of Volcano. There are a great many quartz mines in the vicinity of this town that are thought to be valuable, but are permitted to remain idle and non-productive for the want of a little capital to start the work. Agriculture, horticulture and floriculture have received some attention here, with results about on a par with what has already been described at other places in the county.

The Lumber Interests.

From Volcano east to the summit of the Sierras there is not much agriculture, although in many of the valleys hay is raised in great abundance, but the principal interest is the great abundance of timber, principally pine and cedar. There are some four or five saw mills that are daily turning out large supplies of lumber, besides the great number of saw logs and mining timbers that are daily floated down the Mokelumne river and the different canals to mines and mills in the lower part of the county. This industry, now a very valuable one, is destined to become much more important as the county increases in population and wealth, as it will be sure to do when the enterprising people of the State become better informed as to the natural advantages and resources of this region.

Silver Lake.

This lake is located in the extreme eastern portion of the county, on the summit of the Sierras, and near the Alpine county line. It is a beautiful sheet of water about six miles in length, surrounded by lofty snow-capped mountains, embordered by ragged rocks and gigantic trees, waterfalls and glaziers, rare botanical specimens, unique and beautiful varieties of mosses and ferns, and everything that could be conceived to add to the grandeur and sublimity of the scenery. The fishing and hunting is splendid, the climate cool and refreshing.

One of the curiosities to be seen here is the architecture displayed by a large black ant on many of the large cedar trees found here in great abundance on the hillsides. They bore or cut into and through the trees, forming halls and cross halls and rooms of different sizes, displaying much precision and system in their excavations. They even form stair ways by which halls and rooms above are reached, going up until the tree is so weakened that it falls or they are driven out from some other cause. The ant is about one-half an inch long, with stroug jaws, teeth on the sides, and operate when cutting a little like a pair of scissors.

A good hotel is being opened near the lake for the accommodation of tourists and those who desire a nice, cool and quiet summer resort.

Two miles beyond Silver lake is Dr. Caple's lake, much smaller than Silver lake, noted for its very large spotted trout—splendid beauties and easily caught. There is good hotel accommodations at this lake. These lakes are reached by the Amador turnpike, which passes clear through the county from Ione City to the eastern boundary. The distance from the terminus of the Amador railroad at Ione City to Silver lake is 60 miles, with plenty of feed and water and camping facilities all along the road.

Jackson, July 1st, 1878.

The Proposed Lectures at the College of Agriculture.

The Professor of Agriculture at the State University informs us that he has received but one application for admission to the free courses of lectures on agricultural topics which have been proposed for the coming winter at Berkeley. It can hardly be that there is but one man in the State who desires to have his thoughts and spirit of investigation set in motion in agricultural science. As we pointed out at length a few weeks ago these lectures could be made of great practical value to all agricultural thinkers and workers who can arrange to attend them. We doubt not there will be defined, in each specialty which is taken up, the latest achievements in the application of scientific truth to practical agriculture. Thus there will be a fine opportunity to get possession of new facts or to discern new bearings for old facts. Doubtless the reason there has been but one application for the course is owing to delay in deeds which should have been done at once upon the giving of the invitation. Thus it was in our case, and we shall enrol ourself at once and expect to be both instructed and entertained by the discussions of industrial science. We think there are hundreds of young men in the State who will do well to follow our example, and thus enable Prof. Hilgard to proceed with his preparations.

In the course of the circular which we published in full in our issue of June 29th, the wish is expressed to give "a full course of instructions in the details of the several cultures constituting the various branches of husbandry: such as dairying, stock breeding, horticulture, fruit culture and the manufactures connected therewith, the growing of grain, forage, textile and other field crops, general farm management, etc. It is therefore intended to engage as lecturers in the several specialties competent persons, residents of this coast, thoroughly familiar with the peculiar circumstances, practice and needs of California agriculture. More detailed announcements cannot of course be made until a sufficient manifestation of interest shall have rendered probable the attendance of such number of students as will justify the expenditure, and definite arrangements with lecturers. Applications for admission should therefore be made as early as possible, so that the opening of the course may not be delayed too far beyond that of the session, which begins August 8th. Students may if desired attend only a part of the lectures to be given, and may also attend such other lectures and exercises in the University as they may be qualified to pursue profitably, and without interfering with the progress of the regular classes. In this, as in other respects, they will be subject to the general rules governing the attendance of special students, or of students at large, as the case may be." Communications on the subject should be addressed to E. W. Hilgard, Professor of Agriculture, Berkeley, Cal.

The Engineer.

Deep Water in Carquinez Straits.

The Antioch *Ledger* of last week gives an account of a survey of Carquinez strait, just made by Gen. B. S. Alexander of the Coast Survey, showing that the north channel of Carquinez strait has been deepened seven feet. The following is the statement in the *Ledger:* In 1874, when Capt. Plummer, brought his ship *El Dorado* to Antioch to load with wheat for Liverpool, the Oakland, Vallejo and Martinez papers said there was not sufficient depth of water for the vessel to return. They were no doubt honest in publishing this erroneous statement, as the Coast Survey chart showed that at two points, namely, opposite Seal island and near Brown's island, below Antioch, there was but 14 and 17 feet of water at low tide; hence it was thought to be imprudent for owners to risk their ships in passing heavily laden, across these shoal points. The survey from which these figures were taken was made in 1867. A sounding of the channel in 1874, however, disclosed the fact that the channel had deepened and the result was that Capt. Plummer was convinced he could go to sea from here with a full cargo. It being the first attempt, however, the underwriters desired him to complete the cargo at San Francisco, which was done. From 1874 to the present time no vessels have been loaded at our wharves.

During the present week Gen. B. S. Alexander, Chief of the Coast Survey, has made a thorough sounding of the channel from the Straits of Carquinez to Antioch and with the most favorable results. Gen. Williams gratuitously offered the use of his steam launch *Lulu*, and a party consisting of Gen. Alexander, Capt. E. C. Boobar, Warren Bryant, of San Francisco, and Capt. John Turner, J. G. Chase, J. P. Abbott, F. S. McNulty, T. O. Carter, Capt. Geo. Graham, Louis Dahnken and Engineer McDermott, of Antioch, spent Sunday and Monday in sounding the channel. The supposed point of difficulty was in the vicinity of Seal island. At this point there are three channels, known as the South, Middle and North channels. The former, the South, is laid down as the ships channel. On Sunday, soundings were made through the South channel, but only 17 feet of water was found at low tide, which was not a satisfactory showing. The party continued on to Antioch, sounding the entire distance and found not less than 24 feet of water at any point, reckoning at low tide.

On Monday the party returned, throwing the lead from Antioch to the Sacramento river, following the Sherman Island or North channel, which showed from 26 to 40 feet of water. Gen. Alexander expressed the belief that the North channel off Seal island would prove to be deeper than the South channel sounded the day previous, and so it resulted. Where the chart of 1867 showed 14 feet of water at low tide the soundings Monday showed 22 feet, which was the shallowest water found between Benicia and Antioch. This survey proves that during the last 11 years the North channel has deepened seven feet, and also establishes the fact that any vessel afloat can with safety come to Antioch. There is from five to seven feet of tide at the point mentioned, which added to 22 feet would give 27 and 29 feet of water at the point where it has been supposed was the great danger of ships being grounded. Gen. Alexander expressed himself as highly gratified to know that the North channel has deepened, and says that there is to-day a better ship's channel from the Straits of Carquinez to Antioch than that of San Pablo bay.

The St. Gothard Tunnel.—The St. Gothard Railway Company finds some difficulty in obtaining the money necessary to complete its great work. According to the original understanding under which the work was begun, Italy was to have contributed $9,000,000; Switzerland, $4,000,000; the North German Confederation, $2,000,000; the Grand Duchy of Baden $600,000; and the other German States the additional cost. Now Switzerland is asked to contribute as a nation, instead of by states, $1,300,000, on condition that the Northern and Central Railway Company gives $300,000 more, which, it is estimated, will complete the road. Whether these subsides are in addition to those originally agreed upon does not appear in the dispatch. The road will connect Luzerne and Milau by rail, and the division of cost between the nations is supposed to represent the proportion of benefits to be derived by each from its construction. It now requires 15 hours to cross the Alps by the St. Gothard pass in the diligence from Fluelan to Bellinzona.

Mexican Projects. — An exchange says: Opportunities to bid for contracts are rife in Mexico. A bridge is to be constructed over the River Lerma, as a step toward developing trade between the States of Michoacan and Guanajuato. A railway is to be built between Puebla and Izuoer de Matamoras. A rolling mill for railway iron is to be started at Morelia, and a paper and cotton mill at San Miguel de Allende. The State government of Tamaulipas has been authorized to construct a railway and telegraph from Tantoyuquita, or some other point on the Tamesi river, to the city of Valle del Maiz, on the boundary between the States of San Luis Potosi and Tamaulipas.

A Wonderful Railroad.—The *Railway Age* publishes an exceedingly interesting letter from one of the engineers of the Oroya railway, in Peru. It appears that this great enterprise of the late Henry Meiggs is again to be pushed forward, a company having been formed with a capital of $15,000,000, one of the objects being the drainage and working of a silver mine of almost fabulous richness. The short Mineral railway of Pasco, seven miles in length, by means of which the ore is carried to a water power, cost about $172,000 per mile, and no wonder, as it reaches a hight of 14,200 feet above sea level (nearly 5,000 feet higher than the highest railway point on the North American continent, Veta Pass, on the Denver and Rio Grande), and every part of the equipment —bridges, rails, engines, cars, etc., had to be brought nearly 200 miles, over terrible mountain paths, on the backs of mules. Even the rails had to be made in six feet lengths, weighing only 45 pounds per yard, to be transported over the winding, precipitous way, and iron bridges of 80 feet span were carried in proportionately small sections. Contrasted with the labor, danger and expense of such a work, railway building on the prairies seems to be indeed easy and cheap. The gauge of this remarkable road is three feet six inches. Query: What would it have cost if the rock cutting, tunnels, fills and bridges had been made 14½ inches wider.

Central Branch Union Pacific.—An exchange says that J. H. Beson, the well-known contractor, who did about half the work on the extension of the Central Branch road from Greenleaf to Concordia, and has the contract for the Beloit extension, states that all the grading on the Beloit extension will be finished within six days. About four miles of the track west of Concordia is laid. Mr. Besou has also taken the contract for grading on the Central Branch extension from Concordia to Scandia, up the Republican valley. This line has been already located. A contract for the grading of the Central Branch line from Beloit to Cawker City will be let in a few days.

Hudson River Bridges.—It so happens that the two great bridges in progress, one across the East river and the other across the Hudson at Poughkeepsie, are seriously embarrassed by the lack of funds. On the latter very little is doing, and in regard to the first Commissioner Prentice remarked to a representative of the *Iron Age* that unless New York city provided her proportion of the funds, to stop would be the only alternative. As yet work in the engineers' department gives employment to the full number of hands.

Ship Canal Project.—The bill authorizing the Barataria Ship Canal Company to construct a canal from New Orleans to the Gulf of Mexico, and granting the right of way for that purpose has become a law. The promotors of this enterprise are confident that, when this canal is completed, a new and advantageous way of exit to the gulf for all classes of ships will be opened.

New Italian Railways.—The Italian government contemplates the construction of 60 new lines of railway. The aggregate extent of these lines will be nearly 2,500 miles, and their cost is estimated at £33,200,000. It is proposed to spread the execution of the work over a term of 15 years.

The Carrara Marble Quarries. — The famous marble quarries of Carrara, although they have been worked since the reign of Augustus, and have furnished a steady and enormous supply to the whole civilized globe, seem to be inexhaustible. They compose an entire mountain range, and embrace every variety and quality of marble, from the coarse, common kind to the statuary marble, Monte Crestola and Monte Sagro yielding the largest and finest blocks. The blocks are detached, drawn out by oxen, and rolled down the hill. The quarries number some 500, only about 20 of them furnishing the marble used by sculptors. Most of the inhabitants of Carrara and the vicinity—some 6,000 workmen in all—are employed in the labor, at two to three lire (40 to 60 cents) a day. The marble taken out year before last was in the vicinity of 120,000 tons, valued at $2,400,000, of which 40,000 tons came to the United States. The export of marble to this country has increased immensely within 12 to 15 years, the third largest marble firm now at Carrara being American. Our Consul there is a member of the firm, and his Consulate is said to produce a larger revenue than any other in Italy.

Metallurgy in the Bible.—Prof. Becker, of the University of California, in the course of his lectures last year before the College of Mines, stated in a general way the results of some investigations he had made into metallurgical references in the Old Testament. In the English translation, references to metallurgical processes make, to use the expression, very little sense. However, with the assistance of an Oriental scholar, the Professor found that the old Hebrew writers seemed to understand what they were talking about, and that the apparent ignorance displayed in our version may be laid to the account of the translators. This is a very interesting subject, and at some future time the Press will develop it more fully.

The Largest Plow in the World.

How vain is boasting! Here comes a railroad journal, the *Railway Age*, and, with victor's tone, voices this paragraph:

The largest plow in the world, singularly enough, is one just built, not for a "large farmer" but for the granger's *bete noir*, a railway company. The Chicago, Milwaukee & St. Paul has ordered it to use in ditching for railway construction in Iowa, and it is to be drawn neither by horse, ox or mule, but by a locomotive. The dimensions of this steam-pulled ditcher are given as follows: The share weighs 382 pounds, the mold board 180 pounds; the beam, 900 pounds; the coulter and clasp, 150 pounds; the clevis, 60 pounds; the standard, 134 pounds. The sizes of the principal parts are: Beam, 16½ feet long, 10 inches wide and 17 inches thick; land slide, 9 feet by 5x2 inches, standard, 40 inches by 7x1½ inches; mold board, 8 feet by 2½ inches; share, 5½ feet by 12 inches. It will cut a furrow 37 inches wide.

This puny, one locomotive implement is then put forth as "the largest plow in the world," and the agricultnro of the country seems to have kneeled in silent acquiescence in the railroad's claim! We have waited in the hope that California prowess would not be needed to crush such a tiny upstart, but if the rest of the country holds its peace, California does not. The fact is that California agriculture can so far overlie this mooted monster in the plow line, that if the Iowa plow should fall into the California furrow they would have to get a lantern to find it with.

A few years ago a plow was built on the Livermore ranch in Kern county, according to the design and under the supervision of Mr. W. H. Souther, which, if it should meet this Iowa plow, it would serve it as a locomotive might a hand-car. It is called the "Great Western," and these are its weights and measurements: Beam, 18 feet long, 18 inches deep and 10 inches thick; landslide, 17 feet long, 5 inches wide and 1½ inches thick; standard, 3 feet high; mold board, 12 feet long and 3 feet high. This plow weighs one ton and is swung, by a heavily ironed wooden arch, between two wheels eight feet in diameter and with tires six inches wide. The attaching of the body of the plow to this arched axle of the wheels is accomplished by running two heavy fenders back from the arch, and fastening them to the back ends of the beam and mold board. A 14-foot lever runs from the mold board across the back end of the beam, and on this a man stands to adjust the plow as to depth of cut, etc. The "Great Western" cuts a furrow four feet wide and three feet deep, and is drawn by 80 oxen, yoked to a wire cable one inch thick. This cable weighs 1,140 pounds.

There follows the plow a A shaped scraper, drawn by a chain from its apex by 80 mules. It is 12 feet wide and 3 feet high at the open end. The sides are heavy iron. This, following the plow, shoves the furrow out 10 feet from the place it is left by the plow.

With the "Great Western" and its scraping follower, the Kern Island canal and many of its branches or sub-canals were built in one quarter the time that it could be done with any other machine now in use, and for a much less sum of money.

Such are the facts in brief, for we have not aimed to describe the machinery in full. The lesson which our Chicago contemporary should draw is the beauty of speaking with becoming modesty, and when an Iowa railroad constructs a little cultivator to scratch along the sides of its tracks, do not again call it "the largest plow in the world."—*Pacific Rural Press.*

Professional Men.—The pursuit of agriculture presents a far more certain field for earnest work, or for educated men, than either law or medicine. As illustrating this point, we are in receipt of useful statistics, showing the careers of 1,000 graduates of a great medical school in England, carefully watched through a long series of years, with the following result: Nine per cent. of the number achieved success of sufficient magnitude to be classed as prosperous; 30% gained a moderate competency, and 61% either failed, more or less completely, died, or went out of the profession. Both in this country and in England professional men often have to spend the best portion of their lives in waiting for opportunities. Lawyers and doctors seldom make enough to pay their living expenses before they are 30 to 40 years of age, and it is difficult to account for the strange infatuation which leads many young men to attempt to force their way into such overcrowded professions, which nature never intended them to fill. However, the general depression in business is gradually educating men to the necessity of honest toil for securing their daily bread.—*Cultivator.*

Manufacture of Iodine.—The sea weed is reduced to ash in closed vessels to prevent loss by volatilization, iodine being very volatile. The ash is leached and the liquors are concentrated and cooled, in order to crystallize out the sulphates, chlorides and carbonates of potassium and sodium, and from the mother liquor the iodine is extracted, either by heating with concentrated sulphuric acid, with or without manganese dioxide, or by precipitation as copper subiodide by iron and a salt of copper, from which product the iodine is expelled by treatment with H_2SO_4 and MnO_2. Use of H_2SO_4 without MnO_2 may lead to loss of iodine. Chlorine is also sometimes used to precipitate the iodine from the mother liquors. Excess of chlorine should be avoided. Washing and resublimation prepares the product for market. Cadmium and potassium iodides are used in photography. Iodine is employed in the manufacture of the aniline colors, also in many departments of medicine.

Useful Information.

How to Make Damask Steel.

The *Jeweler* translates from a German source the following definition of "damask steel" and method of making it: Under damask steel is understood a welding or union of steel or steel and malleable iron possessing different quantities of carbon. If the blank and clean surface of a piece of steel is exposed to a weak acid the parts which have little carbon will be more corroded than those which are richer in that substance, and those peculiar dark and light lines, depressed or elevated, and more or less regular, will be observed, which are known under the name of damasks. There are two kinds of this steel, the real or Oriental, which is a natural quality of the raw material, and the artificial, which is formed by the welding, in fine threads together, of the raw material, steel and iron bars.

The material from which the genuine Oriental Damascus steel is made is known in commerce as wootz, or Indian steel, and also from some kinds made in Persia having similar qualities. Wootz is manufactured by first making carbonated iron out of granulated magnetic iron, in small furnaces heated by charcoal. The balls are hammered out into bars which contain 12% of pure rod iron. These rods are divided into small pieces and about 0.5 of a kilogramme of these put into earthen pots with an addition of dry chips of a kind of cassia wood (*Cassia auriculata*) and a few green leaves of the *Asclepias gigantia* or of a kind of convolvulus (*Convolvulus haurifolius*) and these pots are then carefully closed with earthen covers. Some 15 or 20 of these pots are submitted to a strong heat in a small blast furnace, by which means the carbon of the burned plants unite with the iron and a melted carbon of iron is produced. The process is completed in three or four hours, when the steel is once more melted and allowed to cool in the pots. The steel obtained in this way is red, short and brittle, and cannot be refined on account of its considerable carbon. It is, therefore, kept for some time in a simple blast furnace which causes it to lose its carbon. It is then carefully hammered out. The chemical and physical qualities of wootz are not sufficiently known; it contains, according to the latest chemical analyses from 1% to 1¾% of carbon, with some silicon, manganese, nickel and wolframium. This steel is naturally exceedingly hard, and it requires Oriental patience to work it. It is greatly used for sword blades, and in its unhardened state is also much used for gun barrels. There are three forms in which raw steel or wootz is found; in bullet-shaped pieces of about 0.14 of a kilo, as they cool in the pots, and which come from Calcutta in cakes weighing about two pounds and a half, from Bombay, and in cylindrical rods of about the same weight from Golconda. Indian steel has been imitated in Europe in the following way: Small pieces of very good forged iron or steel are put in a crucible and covered with charcoal. Air is carefully excluded, and the mass exposed to heat until it turns dark gray (carburet of iron), this is easily pulverized, and in this state it is mixed with pure alumina and subjected for a long time to a white heat in a crucible, when it becomes white and brittle. If one-sixteenth to one-twelfth of this white mixture is melted with some good steel, a very close imitation of Indian steel is obtained.

Impervious Cloth.—The *English Mechanic* says the Gastuch, or gas-cloth, is a name given by Dr. Hirzel, of Leipsic, to a gas and water-tight stuff, which he has recently patented. This is produced by placing a large, smooth piece of so-called gutta-percha paper between two pieces of some not too coarse and dense material—*e. g.*, shirting (undressed)—and then passing the arrangement between heated rollers. The outer pieces of shirting combine in the most intimate way with the inclosed gutta-percha to form a material which is impenetrable by gas and water. It may be made still denser and more resistant by being coated on both sides with, *e. g.*, copallac. The substance is conveniently flexible, and will remain proof against variable influences of weather and external temperature. It can be applied to all those purposes for which water-proof material is used, and it is well adapted to form gas-tight membranes for regulators of pressure of compressed gas, bags or sacks for dry gas-meters, as also dry gas reservoirs.

To Preserve Leather from Mold.—Pyroligneous acid may be used with success in preserving leather from the attacks of mold, and is serviceable in recovering it after it has received that species of damage, by passing it over the surface of the hide or skin, first taking due care to remove the moldy spots by the application of a dry cloth.

Cooling a Journal.—A very ingenious as well as simple method of cooling a journal, consists in placing an endless belt of loose water-absorbing texture on the shaft, as near the heated part as may be, and allowing the lower right to run in cold water, which may be held in a vessel at a convenient distance below the shaft.

Waterproof Glue.—Fine shreds of India-rubber dissolved in warm copal varnish make a waterproof cement for wood and leather.

To Weaken the Hair Spring.—F. Kemlo says that this is effected by grinding the spring down. You remove the spring from the collet, and place it upon a piece of pivot wood cut to fit the center coil. A piece of soft steel wire, flattened so as to pass freely between the coils, and armed with a little pulverized oil-stone and oil, will serve as your grinder, and with it you may soon reduce the strength of the spring. Your operations will, of course, be confined to the center coil, for no other part of the spring will rest sufficiently against the wood to enable you to grind it, but this will generally suffice. The effect will be more rapid than one would suppose, therefore you will watch carefully, or you may get the spring too weak before you suspect it. Another and perhaps later process is as follows: Fit the collet, without removing the spring, upon a stick of pivot wood, and having prepared a little diluted nitric acid in a watch glass, plunge the center coils into it, keeping the other parts of the spring from contact by holding it in the shape of an inverted soup skirt with your tweezers. Expose it a few seconds, governing the time, of course, by the degree of effect desired, and then rinse off, first with clean water and afterwards with alcohol. Dry in the sun or with tissue paper.

Awards to Americans at Paris.—A dispatch from Paris says that nearly all class juries of the exhibition have finished their work and submitted their reports to the group juries. The latter have passed upon the reports thus far presented, making very few changes. Nothing is officially known of the result, but it is unofficially stated that the Americans have obtained more prizes than the citizens of any other country, in proportion to the number of exhibitors. In one class all American exhibitors have obtained medals, and in another all except one. It is thought the United States will have five or six grand prizes, and a liberal number of gold medals. The foreign jurors have expressed much admiration for the excellence of the articles in the American section of the exhibition. The general commission has increased the number of gold medals 20% silver medals 40%, and bronze medals 60%.

Prussian Blue on Wools.—The *Muster Zeitung* gives the following recipe for 50 pounds of clean wool: To hot water contained in a tin vessel add 1½ pounds oxalic acid, 1½ pounds tartar, 1½ pounds tin salt; ½ pound tartaric acid. Add the acids to the bath first. When solution is complete, add 3½ pounds red prussiate previously dissolved in hot water. Enter the wool, and beat the bath gently, so as to get up to 200° Fabr. in an hour. Then lift out the wool, and to the bath add 4½ pounds sulphuric acid and 1 pound of tin salt previously mixed with cold water; again enter the wool, and regulate the heat so that it will come to the boil in about a half hour. Let it boil for another half hour, and the operation is complete. The *Textile Manufacturer*, noticing this process, states that the samples accompanying the recipe looked very well.

Testing Diamonds.—A simple method, according to an exchange, of discriminating between real and spurious diamonds, is to immerse the specimen in water. If a genuine diamond, it will sparkle with almost undiminished light and brilliancy of color; but if it be spurious, whether paste or rock crystal, the "fire" of the gem will be completely quenched. Another simple test is to draw a small steel file across the stone. If real, the stone will not be hurt; if imitation, it will be badly marred.

Castor-Oil as a Dressing for Leather—Castor-oil, besides being an excellent dressing for leather, renders it vermin-proof. It should be mixed, say half and half, with tallow or ocher oil. Neither rats, roaches, nor other vermin will attack leather so prepared.

Good Health.

Recipe for Hydrophobia.

Editors Press:—As dog days are here again, a recipe for hydrophobia will not be amiss, and here is one that I have known to cure. Take one-half ounce of "henbet" or chickweed and one quart of strong beer; put them in a new earthen dish or vessel; boil it down to a pint, stirring it all the time. Then put in half pound of honey and let it boil right hard. Then strain through an old white cloth, that has never had any grease about it, into an earthen dish that is perfectly clean—then let it stand until cold—enough to put in a bottle. The preparation is then ready for use. Take it in three doses—one dose each day before breakfast. If there is any poison in the system, it will make the patient deathly sick for a little while, but if the bite was harmless it will not affect them more than water. For a child under 12 years old, a gill will be enough. The patient must not eat anything for three hours after taking, and take it on an empty stomach, and eat no sauce that is greasy nor do any work for two weeks. The "henbet" wants to be cut when there is no dew on it, and cut it about the 20th of June, as it is then ripe enough. The plant has a small viny stalk with red flowers, somewhat resembling the henbane, the pest of the gardens in the East, but that has white flowers.

Etna, Cal., July 28th, 1878.

The Safety in Fresh Fruits and Vegetables.

Julia Colman, in her hygienic writings for the *Phrenological Journal*, says: Much more frequently than we suspect, do we allow our food to approach the boundary line of poisonous decay. Cases can be quoted to show that moldy bread and moldy cheese are poisonous. The warmed-over beans and potatoes are not so good as the fresh, because they have lost some of the qualities that recommend them for food. Warm them the second time and they are worse yet. In fact, freshness is a much more important quality in our food than we have been in the habit of supposing. We allow that decayed fruits and wilted vegetables are not wholesome food, but we are slow in learning where to draw the line. We understand in the case of animals that vitality preserves from decay, and we note when an animal is alive and when it is dead, and we should do the same with vegetables, though for a different purpose. The vitality of vegetables is something which can enter into harmony with ours, can feed and nourish it. We do not always need to kill it; we might perhaps with propriety say that we transmit it into our own vitality.

The vitality of fruits is easily ascertained, for when they die they begin to decay. Sometimes a local injury causes a local decay, but the latter soon infects the whole structure, and this is one reason why a partially decayed fruit is wholly unfit for food. Many fruits retain their vitality for a long time after they are removed from the stem on which they grew. There are many varieties of apples, pears and other fruits which do not even mature until some months after their proper period for harvesting, but the vitality is definite enough. Kill that by heat or frost, and there soon follow changes of structure, indicating plainly enough the loss of vitality. Not only is their appearance more attractive when alive and their taste more delicious, but their refreshing and satisfying effects are much more evident. They bring a feeling which is better than stimulation or exhilaration.

Antiseptic Properties of Borax.—According to the *Lancet*, at a recent meeting of the Academy of Sciences of Lombardy, G. Polli reported the results of numerous experiments in which beer, meat, blood, eggs and urine were treated with boracic acid and borax for 30 days during the summer time, and were found still to retain their freshness and to present no traces of fermentation having taken place in them. In experiments, on the other hand, without the addition of the salt, but in some cases with the addition of sulphate of soda, the fluids passed into a state of complete decomposition in the course of 15 days. The energetic disinfecting power possessed by boracic acid and borax, and the facility with which these substances can be absorbed into the economy, led Polli to recommend their use in diseases in regard to the infectious nature of which no doubt exists, or in which septic conditions readily arise. He adduces several examples in which the febrile conditions of tuberculosis underwent diminution. No benefit was obtained by Prof. Visconti from experiments made with these remedies in malaria, though other observers have arrived at a different conclusion. In chronic cystitis, the muco-purulent discharge quickly diminished and even altogether disappeared in the course of a few days, and rapid improvement occurred in bad cases of suppurating wounds when they were applied externally. The dose recommended by Polli is 75 grains of boracic acid and 150 grains of borax per diem.

Ways of Washing the Face.—There are several wrong ways of washing the face, and but one right. Towel, flannel, sponge are all out of place where the face is concerned. The hands only should be used. Doctor Wilson's directions are: "Fill your basin about two-thirds full with fresh water; dip your face in the water, then your hands. Soap the hands well, and pass the soaped hands with gentle friction over the whole face. Having performed this part of the operation thoroughly, dip the face in the water a second time and rinse it completely. You may add very much to the luxury of the latter part of the operation by having a second basin ready with fresh water to perform a final rinse." But the care of the complexion requires that not only the face, but the whole body shall be daily subjected to the bath. The sponge-bath is, perhaps, the best, and the temperature of the water must be regulated by the sensations of the bather and by the season of the year. No one can deny the charm of clear, soft color in the cheeks and lips—and it must be an incorrigible complexion indeed that will not yield to the measures that I have recommended.—*Cassell's Magazine.*

Tobacco-Users.—It has become very common to invest chewing-tobacco and snuff in lead-foil. Herr Hockel examined some snuff from a quantity, part of which had been used by a patient who was laboring under a severe attack of lead poisoning, and found that it contained 2½% of metallic lead. The tobacco near the corners of the package, being more perfectly inclosed by the foil, contained the most lead, which is decomposed by dampness and remains in the tobacco or snuff in the form of carbonate of lead, which is the white lead paint of commerce, which inflicts such horrible sufferings on many of those whose business compels them to work in it.

MISCELLANEOUS.—The Proposed Lectures at the College of Agriculture; The Carrara Marble Quarries; Metallurgy in the Bible, 86. The Largest Plow in the World; Professional Men; Manufacture of Iodine, 87. The Mining Debris Trial, 81.

NEW ADVERTISEMENTS.

Assessment Notice—Vigorit Powder Co., Jas. W. Baker, Secretary, S. F.

The Week.

The usefulness of the University of California has, this week, been increased by the gift, from the Reese estate, of a $50,000 library. The amount is not strikingly large; some have been audacious and unthankful enough to say that, considering its source, it is altogether too small. Nevertheless, we, representing the mining and general scientific interests of the Pacific coast, and having an earnest wish for the advancement of our conntry in every good thing, cannot fail to see in this bequest the most important event of the past seven days. In this act is illustrated the principle that is to redeem us as a nation from the evils that blacken our skies. Desperate love of money and hastening to be rich, have occupied the hearts and the hands of too many for too long a time. The concentration of wealth has done much to reduce the less fortunate (?) classes to ignorance and vice. And ignorance and vice, not keen enough to discover that the true cause of their misery is inherent in themselves, throw all of the blame for present troubles upon the wealthy. But here, concentrated wealth acknowledges the claims of the race upon it, and, wise enough to discern the wants of the people, lays her treasure at the feet of education. She recognizes not only education, but the *higher* education, as it is pushed onward and upward by the unfailing aid of books. Whatever branches may he favored by the Regents, as they dispose of this bequest, our coast and our country cannot fail to be incalculably benefited.

The Quicksilver Workings of California Misrepresented.

There is perhaps hardly a country in the world about which there have been so many erroneous statements circulated, as about California. Its climate, its resources, its people and their social habits, have been flippantly described, frequently hy pcople entirely uninformed about the subject on which they wrote, and these statements once in print, appear quoted again and again by persons haviug no means of testing their truth, until some of them become what may be called proverbial falsehoods.

Curiously enough, the very industries for which our coast is particularly interesting, its mining and metallurgy, shares in this universal misrepresentation. As an instance of this, we will cite the metallurgy of quicksilver, about which we have seen more misstatements than about most of the others of our metals. There is hardly a work which treats of the subject that we have seen in English, French or German, which does not repeat as existing at the present time, methods and processes long since abandoned.

For the sake of illustration, we take an article which appeared in the *Metallurgical Review*, for March, 1878, entitled "Mercury," by Daniel de Cortazar, of the Royal Spanish Mining Department. The article is from the advance proofs of the Official Report of Group I., at the Centennial Exhibition. The facts presented and statements made are in the main founded upon what was to be secn of our resources at the exhibition. Mr. de Cortazar, of course, made the best of the material he had at hand, and he certainly is not to be blamed if Californians were careless enough not to make a proper exhibit. We spoke very strongly against such neglect on the part of our mining men at the time, foreseeing that just such misrepresentations would arise. It is, therefore, not in any spirit of captiousness that this article is written, but in order, as far as possible, to correct any mistakes, and to add any facts that lie in our power. We shall quote such passages as are erroneous, and append corrections to the paragraph quoted. If we are thus able to prevent further circulation of erroneous statements, or to create a little more devotion to the scientific study of technology among the men who are making large fortunes out of our mining propertics, we shall be content.

The first error we noticed, probably a typographical one, was the statement that "it (mercury) boils at 77° Fahr." The boiling point of mercury at the ordinary pressure of the atmosphere, according to Regnault, is at 350° C., or 662° Fahr. Next, speaking of its industrial uses, that for amalgamation is rightly mentioned as the chief one, but it would certainly not have been out of place to have mentioned, not to say anything of its other uses, its use for the preparation of vermilion. For this purpose alone, California exported in 1876, 24,526 flasks; in 1877, 31,210 flasks of 76½ pounds, early, or nearly half of the total amount.

The author then goes on to state how poor were the American exhibits at the exhibition. Were it not for some collections made by the Smithsonian Institution, and by the Central Pacific Railway company, we should have been entirely unrepresented. What little there was, of course, did not enable anyone to make a thorough study of the subject. On the other hand "Spain, without doubt, presented at the Centennial Exhibition the best and richest samples of mercurial ores. The directors of the well-known Almaden mines sent to Philadelphia a complete collection of the various ores, classified according to their richness, from crystals and compact cinnahar to sandstones and slates, in which the mercury was found in small globules, or the cinnahar was seen in nearly imperceptible spots in the rock. They also prcsented the rocks of the country, in connection with the mercurial ores, the metal obtained, and the models of the *aludels*, or small clay vessels of special form, in which the condensation takes place, as well as statistics, plans of the mine and furnaces, hy which the extent of the workings and importance of the mine, the profits, and all the circumstances belonging to an establishment of great interest, could he seen at a glance." One cannot hut be struck hy the large-mindedness of these Spanish gentlemen, which stands in strong contrast to the want of public spirit among certain of our own people.

To continue, this statement occurs: "The principal factories of quicksilver are to he found in Almaden, in Spain, in Santa Clara county, California, in the United States, in Idria, Austria, and the Duchy of Zweihruecken, Bavaria. It is said that, lately, quicksilver ores have been plentifully found, and are being used in Borneo."

With regard to the production in California, quicksilver is found not only in Santa Clara county, hut in Solano, Sonoma, Napa, Lake, Trinity, Fresno, San Luis Obispo, and Cerro Bonito. In 1877, Santa Clara county produced 30,320 flasks, all other counties, 48,280 flasks; total, 78,600 flasks. The Borneo mines were worked hy an English company, hut, from reports received in 1876, proved unprofitable.

The author speaks of the retort process of the late Dr. Ure, combined with a system of condensation by contact with water, as having been "a great improvemcnt." It has, so far as we have learned, not proved so in practice, and is reported to be entirely out of use. This, however, we have no certain means of knowing, as in the following:

"The ore produced from the mines of Santa Clara county, in California, is cinnabar, mixed with a small quantity of mispickel and gray copper ore. Ferruginous slates, often very brittle, form the vein stones, and are accompanied hy limestones and sandstones, and all these rocks are altered by an eruption of serpentine." The above is rather too vague to be criticised. Without eutering into this subject, as we propose doing on another occasion, we would remark that, so far as we know, "mispickel and gray copper" ore, if found at all, have been so in extremely small quantities. Iron pyrites there is frequently in abundance, hut arsenic we do not remember to have seen any traces of. The slate rocks are hetter described as decomposed black slate, frequently almost a soft clay, and rotten rather than brittle. They lie upon the cinnabar and form the "hanging wall," or alta," of the Mexican miners. Beneath the ore bodies, and extending as far as has been worked, is the serpentine. The ore may, thereforc, be described, at least at Almadcn, as lying in between those two rocks, in the form of an irregularly-warped surface. The limestone is dolomitic, and is evidently the result of crevice infiltration. The sandstone is not general. We have not, at present, time for further remark upon this subject.

The ores, by the way, are not concentrated hy washing, as is stated, but by screening, only. The "adohe furnace," which the author describes, is no longer used, as it is inconvenient on many accounts, is intermittent in its action, requires extra labor to make the adobes, or hricks, etc. The preseut system at Almaden is a shaft furnace, on the principle of the Rumford roasting kiln, exactly similar to the furnace iu use in Idria, Austria. The ore is fed by a Parry cup and cone, and discharged beneath the fire-bridges, which brings the flame into the column of ore from the fire-places at the side. In this way, there is no escape of fumcs in charging, and, as the roasted ore descends for some distance bencath the fire-bridge, it is thus not only freed from all traces of mercurial vapors, but the heat contained in it is also saved. This furnace is used for roasting the coarser ore. For the finer ore, there is in use, at present, a shaft furnace, with an arrangement of inclined shelving of fire-clay, according to the patent of Huetner & Scott. These two systems of furnaces, it is unnecessary to say, are as nearly perfectly adapted to their purpose as it is possible to make them, and the results which they have given are in every way satisfactory. The condenscrs are 20 in number, instead of 12. The chimney at the end of the condenscr is not 90 feet high, merely, but there is an arrangement of ascending brick and wooden flues, which climb the adjacent hill-side, and are terminated by a chimney, the top of which is 385 feet above the grate-bars of the furnace.

The author speaks as follows: "Those mines lately discovered iu the United States, which merit special atteution, are situated, some in Nevada, others in Utah, and many in California," etc.

With the exception of the Steamboat Spring deposit in Nevada, a deposit similar to the Sulphur Banks of California, which was worked for a time at a loss and then abandoned, we know of no quicksilver mines worked either in Nevada or Utah, although it is not impossihle that some ore has heen found in these States.

The following mines are enumerated by our author as being, besides New Almadeu, the principal mines in California: "Enriqueta, Guadalupe, Aurora, St Carlos and New Idria, * * * Sulphur Banks, * * *."

We would remark that the Enriqueta has not heen worked for 10 years, the Aurora is unknown, and the St. Carlos adjoins and helongs to the New Idria. The producing mines in California are 22 in number, including, in addition to those properly named ahove, Redington, Great Western, Oakland, Oceauic and others.

Speaking of the method of treating the ore at the Sulphur Banks, the author states: "The richer specimens of ores and residues are put into retorts with lime, as is commonly practiced at New Almaden." This method of treatment with lime in retorts has not been in use at New Almaden for 18 years. Nevertheless, the statement was made once that it was so, and the hookmakers have been copying it from each other ever since.

He gives the following as the production of quicksilver in the whole world:

	Flasks.
United States	69,200
Spain	41,700
Idria	8,000
Bavaria	2,000
Italy	1,700
Borneo	2,000
Mexico	500
Other countries	1,500
Total (flasks of 76½ lbs. each)	126,000

We would remark that the amount of quicksilver produced in the United States, as given hy statistics in the possession of Mr. Randol, manager of New Almaden, to whose kindness we are indebted for many of our facts, is 75,000 flasks for 1876, and not 69,200. This would make the grand total 131,800 flasks, instead of 126,000.

"In conclusion," our author remarks, "we may say that the metallurgy of mercury appears at a stand-still, and no improvements have taken place in it during these past years, in spite of certain trials, snch as that of Pellet, which promises, in time, good results in so important a branch of industry."

In couclusion, we would remark, that in California, at least, constant advance is being made in metallurgy of mercury. Improvements are being made every year in furnaces and condensers, and while, in the latter, there is, perhaps, room for some improvement at many places, we are informed of certain movements which arc already on foot to render the condensation of quicksilver fumes as effectual, as at present the treatment of the ore is economical.

WHAT AND HOW?

In this column are printed all sensible inquiries relating to subjects connected with mining or relating to any matters of general scientific interest; also the answers to them as dictated by individual experience, or as furnished by correspondents.

Diameter of Hydraulic Pipe.

Editors Press :—As your article of August 3rd calls for communications on the subject of the proper size of pipes to convey water for mining purposes, I give you my opinion and tbe general rule which I adopt, and which has, in my experience, given good satisfaction. The proportion of pipe may be called by some, extra large, but where the conditions under which hydraulic pipe is laid for mining purposes in the country, (California) with all the variations, from a straight line, either level, sloping, or vertical, and the disregard of easy curvcs when the direction is changed, are taken into consideration, it will be found that although in some cases the proportion may be large, yet as a general rulc the greatest percentage of useful effect is obtained.

1st. I insist on a velocity of water through the main not exceeding four (4) fcet per second, as, with this velocity, the effect of changes of direction which the sections or joints of pipes have, as laid on the natural surface of the ground, is but little.

2d. Divide the quantity of water, in cubic feet per second which is to be carried in the mains, hy four, and this will give the sectional area of the pipe in square feet. This is without regard to the head, as it requires a vcry slight head to generate the velocity of four feet per second.

3rd. Find the velocity due to the head by multiplying the squarc root of the head by 8.02. Then, whatever the proportion of four, the assumed proportion of the water in the pipe, is to the velocity due to the head, as found ahove, so will the area of the dischargc nozzle, if only one, and combined area if more than one, be to the area of the pipe, as found by (2).

By these simple rules you will so proportion the size of the nozzle and pipe as to be sure of getting the full value of the quantity of water at your disposal. And it will give you nearly the largest size of nozzle you can use, with a fixed quantity of water, that is, to the best advantage.

Let us see how large a pipe must be required for, say 600 inches, miners' measnre; and also whether one or more four or four and a half inch nozzles can be used.

Allowing, as you have, .0271 cubic feet per second for each inch, if 600 inches are used, then 600 × .0271 = 16.26 cubic feet per second. Tbis divided by four, gives 4.06 as the area of the pipe in square feet. This would give a diameter of about 2.25 feet, or 27 inches—nearly four timcs the area you give.

For the area of the discharge nozzle, find the velocity due to 275 feet head hy (3).

The square root of 275 = 16.58, and this multiplied by 8.02 = 132.97 feet per second, as the velocity due to the head. 132.97 divided hy four, equals 33.24, which is the number of times the area of the discharge nozzle will be contained in the area ofthe pipe.

The area of the pipe will hc, for a diameter of 27 inches, 572.56 square inches. This divided hy 33.24 = 17.2 inches. The area of onc four and a half inch nozzle is 15.9 inches; the area of oue four inch nozzle is 12.56 inches; the area of one four and three-fourth inch nozzle is 17.7 inches. Of course, in conveying water for the purpose of utilizing the pressure as much as possihle at the discharge, the velocity in the main pipe must be much less than when no pressure is required at the discharge. Consequently, the ordinary formulas for the discharge of water through open-end pipes would not apply.

W. W. Hanscom.

San Francisco, August 3rd, 1878.

Dip-Wheel.

Editor Press :—I am a river miner. Please inform me through your paper what size dip-wheel I require to build on a river that ruus ahout 3,000 inches of water the lowest time in summer, the wheel to raise 100 inches of water, 38 feet perpendicular. What size wheel, how large the huckets, and how to apply the river water on the wheel?—Ed. Wilson, Forest Hill, Placer county, Cal., June 9, 1878.

If you will explain more in detail just what you mean to do, and what kind of a dip-wheel you have, we can better solve your problem for you.

Edison's Electric Pen and Duplicating Press.

Edison, during his vacation, has honored our coast with his presence. He has spent so many years working for the advancement of his country, that he certainly deserves a long rest. As he travels, he must meet everywhere evidence of the additional comfort he has been the means of bringing to the people. This was brought forcibly to mind by a visit to Mr. E. A. Dakin, 209 Sansome street, in this city, who has control on this coast and in China, Japan, South America, Central America, Mexico and the Islands, of some of Edison's wonderful inventions. Of these the Electric Pen and Duplicating Press is the most valuable to the public as a labor-savor, and as furnishing to all classes of business men facilities they have never before enjoyed, as is evidenced by the fact, that, during the short two years since its introduction, 18,000 have been called for.

The usefulness of the pen is very apparent, in any business whatsoever, in which any number of copies of documents, or cards, or circulars, or written or printed matter of any kind are required. Lawyers find it very useful. It is employed in railroad and insurance offices and in schools. Wholesale and commission merchants, architects and draftsmen, find it equally useful and are among its best patrons. It is also successfully applied to the printing of music. The agent has a scrap-book in which it may be said without exaggeration, every branch of every business gives proof of the almost universal applicability of the Electric Pen; and the large number of sales which he is making and the amount of job work which he is doing are substantial testimonials of its appreciation by San Franciscans.

If an ordinary type-setter, could, by making his hand go through the motions of writing the copy before him, compel type in the case to fly from their boxes and fix themselves right side up in their respective places in the form, he would then accomplish in some degree that which is done by the Electric Pen. The operator with this pen sits down to a desk, with the copy before him, takes the pen, moves his hand as he would in ordinary writing, and soon has a form as light as a sheet of paper and as effective as if it were made of type-metal. But more than this, if he wants a number of copies of a map, or a picture of any kind, whether a landscape or animal form, or a human face, he needs no stone engraving, nor wood engraving, nor photography; all he has to do is to draw them with the pen as he would with a crayon, and he has a stencil at his command from which an almost unlimited number of copies may be obtained. The Electric Pen is, in fact, a very rapid, and, at the same time, delicate stencil-cutter, the material of the plate being paper.

The manner in which the pen accomplishes the stencil-cutting will be understood from the engraving and the following description:

The Electric Pen consists of a small electro-magnetic engine, mounted upon a frame-work secured to the top of a tube, pointed at the end. Within the tube is a common needle, fastened to the end of a shaft, which is given an exceedingly rapid vertical motion by cams upon the rotating engine shaft. If the pen be held in the manner shown in the engraving, upon a sheet of common writing paper, placed on some soft substance, a letter may be written as easily as with an ordinary pen; but the characters, unlike those formed by the ordinary pen, will be composed of innumerable holes punctured in the paper by the rapid projection of the needle from the tube.

The motive power used to drive the engine of the pen is derived from a voltaic battery, shown in the engraving. This battery consists of two Bunsen cells, the principle of which was discovered by the celebrated chemist, Bunsen, and which, for power and convenience, has never been excelled. A particular form of this battery was especially designed for the electric pen, with a view to economy, and its use by persons inexperienced in electricity. It is provided with a lifting arrangement, whereby the plates may be raised from the exciting fluids, when not in use, thus preventing consumption of materials.

The current from the battery is conveyed to the engine by two wires insulated from each other, and placed in a single flexible cord, thus giving a free movement to the pen.

When the pen is not in use it may be placed upon a stand made particularly for that purpose and accompanying the outfit.

After the pen has done its work, the next in order is to print the copies, and this is accomplished in a very simple way by means of the press. (See engraving).

This consists of a metal base, with a perfectly smooth top, upon which the sheet to be printed is laid. A frame, operating upon hinges and having springs for securing the stencils in position, is brought down upon the bed of the press. A roller of felt, saturated with ordinary printers' ink, thinned with an oil, is passed over the stencil plate; the holes of the stencil become filled with ink, and deposit it upon the paper underneath. The result is a perfect facsimile of the original writing, without the possibility of an error, and presenting an appearance far superior to writing done with an ordinary pen. The printed sheet is then replaced by a blank one, and the same process gone through again, until enough copies are obtained.

From five to fifteen copies per minute can be made in this way, and if the steacil is carefully treated it may be used for printing thousands of copies, and after all that, laid away in good condition for future use. Any kind of work may be done, large or small, in ink of any color, and by any person that can read or write. The cost of operating it is merely nominal, yet its work is neat and reliable. We have said that any kind of work can be done by it. For some work, however, it has a fitness possessed probably by no other machine, viz., for writing the amounts on bank checks and stock certificates, which, if so written, cannot be altered without absolute certainty of detection.

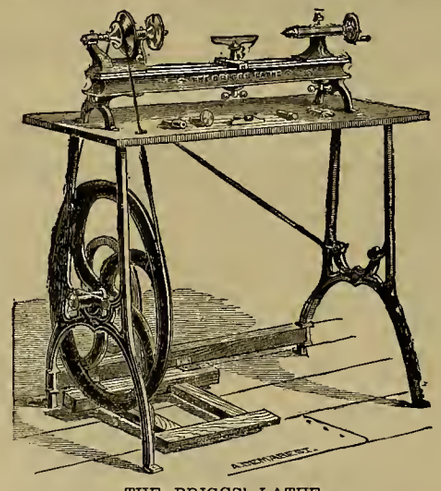
The Overend Feed-Water Heater and Pump.

The object and principle of feed-water heaters are, of course, well understood by all that have to do with the creation of steam-power. If cold water be forced into a hot boiler, there

EDISON'S ELECTRIC PEN AND DUPLICATING PRESS.

arises a loss of power corresponding to the amount of heat necessary to raise the cold water to the required temperature. Moreover, if the exhaust steam is allowed to escape, here is another waste of heat, of power, of fuel. The Overend Feed-Water Heater and Pump prevents both of these losses by using the heat of the exhaust steam to warm up the cold feed-water. This is accomplished as follows:

The machine consists of a large cylinder con-



THE BRIGGS' LATHE.

denser, furnished with inlet and outlet pipes, connected to the cylinder on either side. In front and behind are the pumps, which are run by a belt-wheel on the top of the condenser. The exhaust steam enters the condenser through a large pipe on the right. At the elbow of this

Overend Feed-Water Heater and Pump.

pipe, just before it connects with the condenser, a small pipe for cold water is introduced. Through this small pipe the cold feed-water is allowed to run in on top, as it were, of the exhaust steam. This cold water, of which very little is needed, serves to condense the exhaust steam, and the exhaust steam, in turn, heats the cold water up to boiling point. What little exhaust steam is not condensed, passes off to the left. The condensed steam and heated water fall to the bottom of the condenser where *double-acting* pumps receive them and forces them together at the temperature of 212°, into the boiler. The double-acting feature of these pumps is said to be new; the plunger is hollow. All impurities of the water fall to the bottom of the condenser, and from there they can be removed through a man-hole.

Any oil in the exhaust is blown across the surface of the water in the condenser to an outlet provided for it. So we see that a *constant* stream of *pure* water, *just on the point of being converted into steam*, is supplied to the boiler.

Among the many advantages claimed for this machine, the inventor gives the following as among the most important:

First.—The great saving of water and fuel, a test of one year in a large and extensive steam-power establishment showing an actual saving of 26½% in fuel, and over 50% in water, so that a saving of from 15% to 20% in fuel and 50% in water may be assured under fair conditions. This percentage of saving is over and above the benefits derived from the coil-heater, which was in use before the invention of the present apparatus.

Second.—The boiler, being constantly supplied with pure distilled water, is saved from the destructive effects of scaling; all the sedimentary deposits contained in the water being separated by distillation, are precipitated to the bottom of the condensing chamber, from whence they are easily removed through a man-hole plate.

Third.—The danger of explosion, caused by oil being carried into the boiler, is obviated by the use of this apparatus, there being an outlet for the oil which may accumulate in the condenser. The spray forces the oil floating on top of the water from the center to the outside of the chamber where the outlet is situated, and from which all the oil escapes. This outlet also prevents the possibility of an overflow of water in the condenser and heater, and the bursting of the exhaust-pipe, which is likely to result therefrom.

Fourth.—The pumps may be used separated from the condenser and heater, for pumping cold water or liquids, and the large reserve-pumping power available for any immediate emergency is often a very valuable requirement.

Fifth.—The machines cost about the same as those possessing none of the special advantages herein enumerated.

We saw this machine in operation at 510 Commercial street, San Francisco. The engineer in attendance was very pleasant, showing himself perfectly familiar with the machine and patiently explains its working to all desiring information. Representatives of all establishments using steam-power will do well, if only in the interest of economy, to visit and examine this machine.

CHROME IRON.—We call attention to the article on the above subject in the Mining Summary of this issue. In the next issue we shall have more to say on the subject. Meanwhile, we advise those interested in the San Luis Obispo deposits to send specimens of the ore to the Mechanics' Fair. We volunteered in our last issue, to exhibit specimens sent to our care,

New Book on Arizona.

Mr. E. Conklin, the San Francisco co-representative of Frank Leslie's publications, and of the Chicago *Times*, and agent for the New York *Mining Record*, and Bureau for Mining Information, is about to publish a book on Arizona. Mr. Conklin has the reputation of being a "pusher into new countries." Since 1870, he has spent a fortune in exploring, and making the world acquainted with territory, before little known. He has traveled in the West Indies, in Central America, in Mexico, in the Territories of the United States, including Alaska. While in Mexico, he was one of a party of three that were the very first that ever climed to the bottom of the crater of Popocatapetl. The scenery, he says, was simply beyond conveyance by words. The party were reckless enough to sleep at the bottom of the crater. Mr. Conklin was finally taken out insensible, and carried, in that condition, to the foot of the mountain. During the last Indian war with Joseph, Conklin conceived a great desire to obtain a picture of that chief. He traveled, undaunted, for days, until he succeeded in gaining his purpose. The picture appeared in Leslie's publications. He has passed through stirring scenes, and is well fitted to make an interesting work on such a country as Arizona.

It is promised that the new book shall be thorough. It is the immediate result of extensive travels, both north and south, in Arizona, and will be of special interest to all mining men, through its late and full information concerning the new, much-talked-of Santa Rita mines. Though containing information with regard to all important mining districts of the Territory, it is, by no means, a technical work on mining. As its name, "Picturesque Arizona," implies, it gives us views of that strange country. Many of these views are entirely new, having never before been presented to the public. His complete series of Arizona views has been purchased by the Continent Stereoscopic company, of New York, who are also publishing his book. We shall obtain some of his scenes from Arizona, to publish in the PRESS, at an early date. The book is entertaining in its accounts of frontier and mining life. It will soon be on our coast, and will, no doubt, be eagerly seized by all lovers of travel, and researchers after new and reliable information respecting an interesting land.

The Briggs Lathe.

We give herewith an engraving showing the Briggs lathe, a new one which combines superior excellence in quality and finish, with strength and completeness. This lathe will turn a piece of wood or metal 12 inches long and six inches in diameter. It can be used with equal advantage for drilling, polishing, sawing, etc. The length of bed is 24 inches; the spindle is made of steel, has a conical bearing, and can be tightened as it wears. The bed, head, tail-stocks, and cone-pulley, are of cast-iron, and the centers of steel. The following pieces are furnished with the lathe: Two T rests, one face-plate, two plain centers, one spur center for wood, one plain drill-chuck, one drill-pad, and one center left-blank to turn down as a fitting for a universal chuck. The bench weighs 81 pounds, is made of iron, with a black-walnut top, and has a driving-wheel measuring 22 inches in diameter, with three grooves for changes of speed. The lathe may be seen at Dunham, Carrigan & Co's, of this city.

MECHANICS' FAIR.—The Thirteenth Industrial Exhibition of the Mechanics' Institute will present, it is promised, unusual attractions. As on former occasions, mining, agricultural and other machinery will be exhibited in motion. Pacific coast manufactures, minerals and agricultural products will be fully represented. An effort is being made to have an unusual display of California vine products. Prizes will be awarded by competent judges, among them the Rev. Dr. Bleasdale, of Australia. The San Francisco *Journal of Commerce* is soliciting donations to an exhibit which it will have under its own care. The art gallery will be managed by the San Francisco Art Association. New features will be added to the horticultural garden. And that most popular accompaniment, the music, will be as entertaining as heretofore, if not more so. All this is promised. We trust that the Managers will not disappoint us.

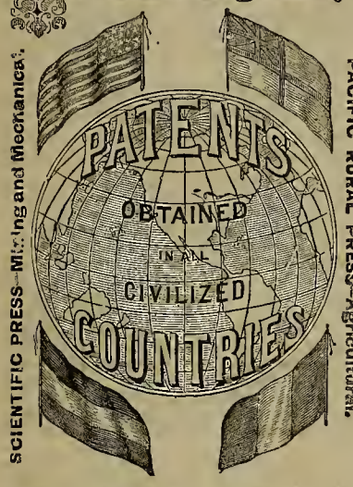
JUDSON POWDER.—We publish in another column several letters from persons using Judson powder, from which will be seen in what great favor that article is held by mining men. It is specially useful for bank blasting, and has been very rapidly introduced, proving that its efficiency was quickly recognized. Messrs. Bandman, Nielsen & Co., agents of the Giant Powder Co., manufacture this powder in this city. The letters referred to will show what has been done with the powder in numerous cases, and we recommend their perusal to the mining public.

ALL parties at work on the San Francisco gold placers seem satisfied that there is at least sufficient to make wages.

DEWEY & CO'S

SCIENTIFIC PRESS

Patent Ageney.



Office—202 Sansome St., N. E. Cor. Pine, S. F

PATENTS obtained promptly; Caveats filed expeditiously
Patent re-issues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing.

The shrewdest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, $7.50.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

MECHANICS' INSTITUTE.

13th INDUSTRIAL EXHIBITION.

SAN FRANCISCO, CAL., 1878.

The Managers have the honor to announce to the public that the Thirteenth Grand Exhibition of SCIENCE, ART and INDUSTRY, given under the auspices of the Mechanics' Institute, will open at the Pavilion on Market, Eighth and Mission streets, on

TUESDAY, AUGUST 13th, 1878.

Great and unusual attractions will be presented to visitors. Mining, Agricultural and other machinery will be in motion. Pacific Coast Manufactures, Minerals and products of the soil will be fully represented, beside many new and interesting novelties never before exhibited on this Coast. The

ART DEPARTMENT

Will be under the supervision of the San Francisco Art Association, a guarantee for excellence and completeness. Local Art will be specially represented, as also works of noted foreign artists, selected from the private galleries of this City. The

HORTICULTURAL GARDEN,

So popular heretofore, will be made still more attractive this year by the addition of many new features.

THE MUSIC.

Each afternoon and evening a first-class instrumental concert will be given by the best soloists and accomplished musicians of this City, with a daily change of programme of the best and most popular music.

No expense or pains will be spared by the Management that will add to the comfort or convenience of visitors.

Applications for space or information can be obtained from the Secretary, at the office, 27 Post street.

IRVING M. SCOTT, Pres't.
J. H. GILMORE, Sup't.
J. H. CULVER, Sec'y.

ST. CHARLES HOTEL,

SANTA CRUZ, CAL.

JOSEPH BLOCH, - - Proprietor.

This popular House, having been thoroughly refurnished and refitted, is now open for the reception of guests as a

FIRST-CLASS HOUSE,

And in the character of its accommodations second to no interior Hotel in the State.

The Hotel Coach will carry passengers from all Trains and Steamers to the House

FREE OF CHARGE.

Two lines of Street Cars pass the Hotel to the Beach and Bath Houses.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco.

To Ship and Engine Builders, Steamship Companies, Etc.

A Mechanical Engineer, having an extensive experience in Marine Engineering (especially compound) and Iron Ship Building, also in Steam Engines and Machinery in general, is open for engagement. First-class references.

Address and references can be obtained at office of SCIENTIFIC PRESS.

SUMMER RESORT.

Exhilarating Climate! Grand Scenery!!

☞Persons intending to spend a few weeks in the country during the summer months should stop at the Bridge House, on the South Yuba. Accommodation may be had for a few more boarders by addressing MRS. R. H. CULBERTSON, Emigrant Gap. House only one mile from the station.

KING ENGINE.

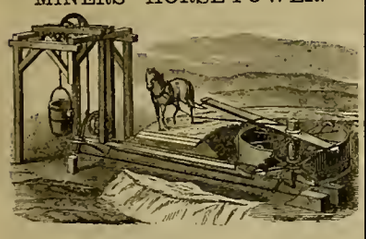
The Only SAFE BOILER. SAVES One-half the FUEL Consumed by Others.

The engine is adapted to all the various industries in which small power is required. The engines are FIRST-CLASS, and are made from two to twelve horse-power.

The smaller sizes are especially recommended for irrigating land, driving printing presses, or manufactories. The larger sizes are being extensively introduced in small quartz mills, where their economy of fuel and portability especially commend them. Send for circular.

REYNOLDS, RIX & CO., Sole Agents,
18 & 20 Fremont Street, San Francisco, Cal.

MINERS' HORSE-POWER.



This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS, RIX & CO.,
18 & 20 Fremont Street, San Francisco, Cal

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:

One man, per day	$ 3 50
One man, per day	3 00
Wood, 1½ cords at $3	7 00
Cost of 20 tons	$13 50
Cost of one ton	67½

From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address:

Judge Wm. Webster, Paymaster Mine, Reno, Nev.
Lewis Chalmers, Manager Exchequer and IXL Mines, Silver Mountain, Cal.
J. S. Cone, Vice-President Tehama County Bank, Red Bluff, Cal.
R. H. Campbell, Superintendent Afterthought Mine, Redding, Shasta County, Cal.

For further information, apply to

Mining Share Market.

Last week was considered one of remarkable activity. The activity has been on the increase during the present week, the whole market being at times wide-awake, but special attention being drawn to the north-end mines, Union Con., Sierra Nevada, Mexican and Ophir. From Monday to Friday, inclusive, of last week, the dealings in Union Con. amounted to 30,735 shares. The business in that stock for only the first two days of this week surmounted the dealings of all five, last week. Monday, the business in Union Con. amounted to 11,210 shares; Tuesday, to 19,980 shares; total, 31,190 shares. Such an increase cannot be reported of any other mine. The cause of this lively condition is said to be two-fold. Union Con. has prospects of its own, in the first place; in the second place, the rich strike reported in Sierra Nevada, is, it is alleged, over the line in Union ground. Whether this be true or not, it is to be hoped will soon be settled.

Meanwhile, this rich strike easily accounts for life in Sierra Nevada. The following is an extract from a letter to the *Daily Stock Report*, dated Virginia, August 7th: "It has been pretty definitely ascertained that the east wall struck the other day by the incline, was not the east wall at all, but a thin streak of porphyry, through which the incline soon passed and disclosed ore of magnificent promise and richness—some say assays going as high as $600 per ton. The management here are as dumb as an oyster, so it is impossible to fully confirm the news, but there is hardly a doubt that it is true."

Ophir has been weakening. Mexican, on the contrary, has been getting rather better. As the week progresses, the excitement seems to be running along the line to the south, California, Con. Virginia and Belcher being moved. Julia has been slowly on the rise.

Mechanics' Industrial Fair.

EDITORS PRESS:—At the request of the Board of Managers, of the Thirteenth Industrial Exhibition, to open in this city August 13th, 1878, we are about to make a display of Pacific coast products and manufactures. It will consist of cereals, fruit, wino, wool, minerals, ores, tobacco, silk, flour, woods, and other objects, natural or cultivated, of curiosity or importance. We invite the co-operation of all, and respectfully solicit those who have fine products to supply us with samples of them. Anything worthy of display in any of the above lines may be shipped to us, per Wells, Fargo & Co., who will carry them free of charge to the Mechauics' Fair building, Mission and Eighth streets, San Francisco. Credit will be given to each party contributing, and if any premium is awarded, it will be sent to the parties sending us the exhibit.

W. H. MURRAY,
Business Manager *S. F. Journal of Commerce* Publishing Co.,
No. 414 Clay street, San Francisco.

What is Said of the Judson Powder.

FOREST HILL, April 1st, 1878.

MESSRS. BANDMAN, NIELSEN & Co., Agents Giant Powder Co, San Francisco:

Dear Sirs:—In reply to your inquiry as to how we were pleased with the Judson Powder: In the first blast we used 24,450 pounds in 12 different chambers in hard cemented gravel; the bank was from 125 to 180 feet high; the powder line 65 feet from the face. This was an entire success, completely pulverizing 240,000 cubic yards, so that there were no hard lumps left of any amount, as was formerly the case when the blastiog was done with common black powder, when there was an entire mass of large lumps of cemented gravel left requiring a great deal of labor; and then the gravel would not be pulverized, and and the gold could not be as readily saved.

The second blast had 11,000 pounds of powder under a 200-foot bank. This did more work per pound than the former blast—say 12 cubic yards per pound of powder. In my judgment, the Judson powder far surpasses the common black powder in quantity of ground moved, also in pulverizing the gravel; then it is not liable to explode, as fire will not explode it, and it requires very little tampering compared with black powder.

I, for one, am very thankful for the invention of the Judson powder, and remain, Yours Truly,

JOS. MCGILLIVRAY,
Supt. Dardanelles Con. G. M. Co.

NORTH SAN JUAN, May 18th, 1878.

MESSRS. BANDMAN, NIELSEN & Co., San Francisco:

Gentlemen:—In reply to your inquiry as to our opinion of the merits of Judson powder: In conversation with our Superintendent he says he is satisfied that Judson powder is the best agent that has yet been introduced for blasting hard cement gravel, and from what we have used of it we are rather prepossessed in its favor. We have up to the present time used about 1,000 cases. In April we fired a blast of 260 cases; the main drift was 70 feet long; the cross drift, or T, as it is called, 100 feet; the bank 125 feet high, 100 feet of it blue cement, and the most of this of the very hardest kind. When we commenced washing on it we were rather disappointed in the execution the powder had done. Still, after we washed the ground away and seen the character of it, we were not surprised that the result was not better. There should have been 300 cases in it instead of 260. Your agent, Mr. White, saw part of the blast, and from him you can learn something of the nature of the ground that the blast was in. Last Monday we fired a blast of 154 cases, which did excellent work. We are now running a drift that will take about 170 cases. We have lately noticed one very good quality of the powder, viz: it works *down* as well as up. This is quite an advantage, for in black powder blasting, if the drifts are not about on the bedrock when the gravel is hard, the bottom is nearly always left, and this we have to blast up. Every Judson powder blast we have put off has cleaned right out to the bottom or bedrock; the T in the last blast was all of six feet from the bedrock. We are satisfied that in hard cement, with an equal show, Judson powder will break more ground and pulverize it better than the black powder will.

We think you can rely on us to use a large amount of Judson powder, unless something turns up to change our present opinion. Hoping this may be of some satisfaction to you, we are, Yours Respectfully,

AMERICAN MINING CO.,
Per J. H. Brown, Secretary.

Office of the North Bloomfield Gravel Mining Co., No. 320 Sansome St.,
SAN FRANCISCO, May 23, 1878.

MESSRS. BANDMAN, NIELSEN & Co., San Francisco:

Dear Sirs:—In answer to your favor of 24th inst. asking my opinion of the comparative merits of Judson and ordinary gunpowder as blasting explosives, I have to say that in bank blasts in hydraulic mining, where the gravel is hard and thoroughly cemented, I regard the Judson powder at the same price as being very much the better of the two. In quite soft gravel the difference is not so great, but still I think rather in favor of the Judson.

In very hard gravel it is desirable not only to shatter the entire mass above the powder drifts, but also to break the gravel into the smallest separate particles practicable. This the Judson does very much more effectually than the black powder, thus not only saving or reducing the further expense of breaking up the lumps of cemented gravel by sledges, but also conducing to an increased yield of gold in the sluices. In this respect I regard the introduction of Judson powder as being of much benefit and economy to the hydraulic mining interest. In blasting in large excavations, such as railroad cuttings, etc., the Judson powder will do better work than any explosive with which I am acquainted, for the reasons above given.

Very Respectfully, HAMILTON SMITH, JR., C. E., Vice-President.

Milton Mining and Water Co.,
Nevada County, Cal.

FRENCH CORRAL, July 23d, 1878.

MESSRS. BANOMAN, NIELSEN & Co., Gen. Agents Giant Powder Co:

Dear Sirs:—Yours of the 19th inst. at hand. We have been using the Judson powder since its first introduction, and find it superior to the common blasting powder. In our hard cement it pulverizes it better and lessens the expense of working it by hand. The black common blasting powder breaking it (the cement) in large bodies which had to be pounded and broken up by hand, in order to make it small enough to be moved by the water and run into the sluices below. The Judson shivers or pulverizes the cement better and it needs less hand-work to pass it into the sluices. With the use of the Judson we catch a larger percentage of our amalgam at the upper end of the sluices, showing conclusively that the cement is better pulverized and more easily washed. In the bank the Judson will break equally as much bank and probably more (equal quantities). I am of the opinion that the great advantage of the Judson over the black powder in back blasting is the manner that it works to the bank, crushing it better and finer than the other. I remain,

Yours truly, V. G. BELL, Sup't.

Important to Manufacturers.

We publish the following extract, believing that the information it contains will prove of material benefit to many business men who will read the facts therein given:

It is customary with manufacturers in England and France to testify their faith in the merits of their own wares by the use of a "TRADE-MARK;" and in all their business communications with the trade and the public to give to it the character and quality of a guarantee of the article to which it is attached.

The advantages derived from such a practice are:

First. The interest of the manufacturer continues to be identified with the character of his wares from the moment they are first placed on the market until they are worn out; and he is always in a position to regulate the conditions of their sale, and to dictate his own prices, both as between himself and the jobbing or commission merchant, and the retail trade.

Second. The best class of the retail trade at first objects to selling goods that bear a fixed mark, for the reason that competition very soon reduces the profits on goods that are widely known; and hence the almost universal practice, with responsible retail dealers in every branch of trade, is to have goods stamped with their own names, and thus, in some measure, protect themselves in the matter of price, and secure an additional profit on their own gnaranty.

Third. The best class of manufacturers and the best class of retail dealers are thus immediately brought into antagonistic business relations, and the antagonism continues until the manufacturer appeals directly to the consumer, asking him to demand his wares of the retail dealer in preference to any other—of course furnishing the reasons for such preference. The retail dealer for a while makes the best resistance he can; but wide newspaper publicity forces him at last to yield—he is forced to respect the demand of the consumer; and finally the reluctant dealer of yesterday becomes the most enterprising merchant of to-day, and he, too, advertises that he has a full line of the popular brand, and is prepared to sell at close prices. Newspaper advertising, in the thoroughness, promptness and completeness with which it does its work, has solved the problem; educating the consumer to ask for what he wants, and to recognize it when he sees it. This is one of the miracles performed by the modern newspaper press in the economy of the world's industry.

Fourth. The absence of a trade-mark reduces the manufacturer to a mere workman for the seller. It matters not how long his goods have been in use by the public; if they are not known he is compelled to meet competition of every kind and is always in a position to be undersold by rivals. Necessity occasionally may force such a manufacturer in order to get ready money to make an extra concession in price; you must make a similar concession or have the sale of your goods greatly delayed. If another rival fails entirely, and his goods are offered at auction, the auction price determines the market value for the time being, and in a country where there are so many failures as in ours, experience has shown that in nine cases out of every ten the auctioneer becomes at one time or another the final salesman for the manufacturer who has failed to protect himself by a trade-mark.

Fifth. Manufacturers who make popular trade-marked goods are, too, sometimes embarrassed, and their wares, also, are offered at forced sales; but the trade have a strong interest in maintaining prices on such goods, and hence ready buyers are always found at a small reduction from former prices, and the trade-mark, which was at first an obstacle to their introduction by the best trade, becomes the very basis for their permanent prosperity.

The Joseph Rodgers & Sons' cutlery is as unique an illustration as it is good of the value of a trade mark. Joseph Rodgers was simply a retail dealer in England. He ordered what cutlery he wanted made with his own name, and thoroughly advertised his wares. The Sheffield makers, noticing his success, paid him a large sum for the exclusive right to the use of his name for their own trade-mark; and thus arose the most popular brand of cutlery in the world. And while it is to-day 50 per cent. dearer than similar goods made at Beaver Falls or in Connecticut, and pays a U. S. government duty of from 30 to 50 per cent., and the usual expenses incident to the trade in this country, still it holds its place and continues to testify to the importance of using a trade-mark and making it as widely known as possible.

A few years since Congress amended our laws so as to issue patents and give more definite protection to manufacturers throughout the United States who register their trade-marks. Also, provisions were made for registering labels in a more secure form than issuing patents for trade-marks. The result is that during the past year or two business has greatly increased in registering trade-marks. So far as we have learned, every applicant for a trade-mark has not only been well pleased with their patent, but in most instances greatly profited.

Manufacturers on the Pacific Coast will do well to seek further information on this subject, and apply for their patents through DEWEY & Co., patent agents, No. 202 Sansome street, San Francisco.

Woodward's Gardens were never more attractive than at present. Besides three lions already mentioned, six monster living alligators, several iguanas and a boa-constrictor have just been added. New stars are constantly engaged for the Pavilion exercises. Rates of admission as usual.

WIRE ROPE TRAMWAYS.

This system of transport is peculiarly adapted for the carriage of minerals over rough countries. Heavy gradients and long spans easily overcome, and cheaper than by any ordinary means.

Transmission of Power by Wire Ropes.

The power of water or steam can by this means be carried for long distances, with great economy.

For estimates and practical information apply to

JOHN SAMSON, Engineer,
No. 743 Pine Street, San Francisco, Cal.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

Take the paper that stands by your interests.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Excelsior Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Potosi District, Lincoln County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Sixteenth day of July, 1878, an assessment of Twenty-five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at the office of the Company, 304 Post street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 20th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the sixth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

FRANCIS P. DEVINE, Sec'y.

Office, 304 Post street, San Francisco, Cal.

Mariposa Land & Mining Company of California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the Tenth day of July, 1878, an assessment (No. 14,) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No 309 Montgomery street, San Francisco, Cal., or to the Assistant Secretary, at the office No. 9 Nassau street, New York City, N. Y.

Any stock upon which this assessment shall remain unpaid on the Twelfth day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth day of September, 1878, to pay the delinquent assessment, together with costs of advertising and the expenses of sale. By order of the Directors, LEANDER LEAVITT, Sec'y.

Office, Room 33, Nevada Block, 309 Montgomery street, San Francisco, Cal.

Seaton Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Drytown Mining District, Amador County, California.

NOTICE.—There is delinquent upon the following described stock, on account of Assessment (No. 11) levied on the 26th day of June, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Thompson, W., Jr.	72	15	$1125 00
Thompson, W., Jr.	79	10	750 00

And in accordance with law and an order of the Board of Directors, made on the twenty-sixth day of June, 1878, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Company, Room No. 58 Nevada Block, northwest corner Pine and Montgomery streets, San Francisco, California, on Wednesday, the twenty-first day of August, 1878, at the hour of one o'clock P. M. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.

JOEL F. LIGHTNER, Sec'y.

Office, Room No. 58 Nevada Block, Northwest corner Pine and Montgomery streets, San Francisco, California.

Office South Comstock Gold and Silver Mining Company. Notice.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of Trustees and the transaction of such other business as may be presented, will be held on Monday, the 19th day of August, 1878, at two o'clock P. M. of that day, at the office of the Company. Transfer books will be closed on Saturday, August 10th, 1878, at the hour of 12 M. of that day.

J. M. RUFFINGTON, Secretary.

Office—Rooms 3 and 4, second floor, No. 309 California street, over Actna Insurance office.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Seventeenth day of July, A. D., 1878, an assessment, (No. 4,) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of said Company.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, A. D., 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tenth day of September, A. D., 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. W CLARK, Sec'y.

Office, No. 318 Pine Street, San Francisco, Cal.

Telegraph Copper and Silver Mining Company.—Principal place of business, City and County of San Francisco, California. Location of works, Gopher Mining District, Calaveras County, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of July, 1878, an assessment of three (3) cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at his office, Room 2, 528 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth (9th) day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

I. T. MILLIKEN, Sec'y.

Office, Room 2, 528 California street, San Francisco, Cal.

Vigorit Powder Company.—Location of works, California City, Marin County, State of California. Location of principal place of business, City and County of San Francisco, California.

Notice is hereby given that at a meeting of the Directors held on the first day of August, 1878, an assessment (No. 1) of fifty cents (50c.) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room No. 1, 109 California street, in the City and County of San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Thursday, the twelfth day of September, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the second day of October, 1878, to pay the delinquent assessment, together with costs of advertising and expense of sale.

JAS. W. BAKER, Sec'y.

Office, 109 California street, Room No. 1, City and County of San Francisco, California.

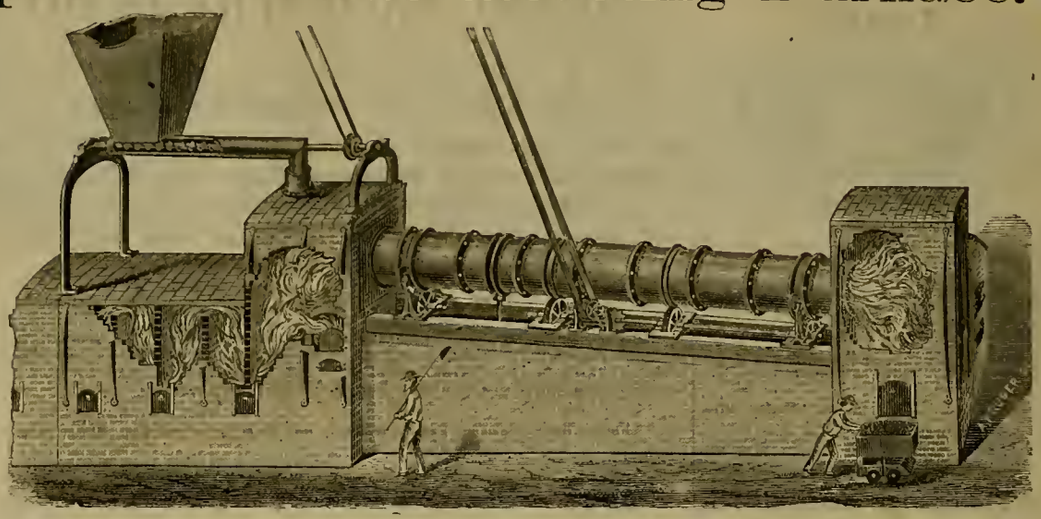
Howell's Improved White Roasting Furnace.



This cut represents the most improved construction of this unrivaled Furnace, the superiority of which, over all others as regards cost and capacity, as well as the economical and thorough oxidization and chloridization of ore, is now generally conceded.

In this Furnace, as covered by the Howell and White patents, are combined the three acknowledged requisites for the thorough and economical roasting and chloridization of ores.

First.—Continuous progression through and discharge of the ores from the furnace—while in the meantime they are, by being constantly showered through the heated air and gases within it, exposed in the greatest possible degrees to their reducing action.

Second.—Subjecting the ores to this showering process any length of time that may be necessary, according to the character of the ore, for its thorough reduction. In passing through the furnace it ordinarily falls about 1,000 feet, all the time in direct contact with the flame.

Third.—Increasing the heat on the ores as they are progressed through the furnace.

In this respect this furnace excels all others, as in none of them are combined all these essential requisites. It will chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade

The first cost, as well as the cost of operating it, is less than that of any other furnace of equal capacity.

It requires no especial skill in management that cannot be readily acquired by any one capable of conducting an ordinary silver mill.

We manufacture various sizes adapted to a five, ten or twenty-stamp mill, and will furnish plans by which any competent mill man can erect and operate it.

This furnace having the full or partial brick lined cylinder, embraces the devices covered by the patent to John Howell, as well as the original devices covered by the White patents. It has been erected and operated successfully at the following mines in California, Nevada, Arizona and Montana, viz: **Camanche, Jefferson, Leopard, Utah, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry, Independence, Endowment and Alice.**

At least ten of them are now in active and successful operation, in some cases reducing ores of the most refractory character.

These facts are a sufficient attestation of the merits of this furnace.

The undersigned, with Mr. John Howell, are the sole owners of the Howell patent, and they have perfected arrangements with him, and also with Mr. J. M. Thompson, who is owner of an interest in the White patents, and as such is possessed of as full and perfect rights and powers under the same as the patentee himself, by which they have acquired the exclusive right to manufacture these furnaces for the Pacific States and Territories. We hereby **caution** all parties against purchasing the same from any others but ourselves, or the said Howell or Thompson, as we shall prosecute all parties infringing upon the same. For particulars, price and terms, address

THIRTEENTH INDUSTRIAL EXHIBITION

—OF THE—

Mechanics' Institute.

San Francisco, Cal., 1878.

The Managers have the honor to announce to the public that the Thirteenth Grand Exhibition of Science, Art and Industry, given under the auspices of the Mechanics' Institute, will open at the Pavilion on Market, Eighth and Mission streets,

TUESDAY, AUGUST 13th, 1878.

Great and unusual attractions will be presented to visitors Mining, Agricultural and other Machinery will be in motion. Pacific Coast Manufactures, Minerals and Products of the soil will be fully represented, besides many new and interesting novelties never before exhibited on this coast.

THE ART DEPARTMENT

Will be under the supervision of the San Francisco Art Association —a guarantee for excellence and completeness. Local Art will be specially represented, as also works of noted foreign Artists, selected from the private galleries of this city.

THE HORTICULTURAL GARDEN,

So popular heretofore, will be made still more attractive this year by the addition of many new features.

THE MUSIC.

Every afternoon and evening a first-class Instrumental Concert will be given by the best soloists and accomplished musicians of this city, with a daily change of programme of the best and most popular music.

No expense or pains will be spared by the management that will add to the comfort or convenience of visitors. Applications for space or information can be obtained from the Secretary, at the office, 27 Post street.

IRVING M. SCOTT, President.
J. H. GILMORE, Superintendent.
J. H. CULVER, Secretary.

VOLUME XXXVII Number 7

The Mining Debris Trial.

[Continued from Last Week.]

Louis Janin, mining engineer, and resident of California since 1851, thought the only proper way to work these mines was by the hydraulic process. Observation had led him to believe that the inhabitants of the mines in this State were more prosperous, generally, than in any other mining district with which he was acquainted. He believed that the stoppage of the mines would not prevent the flow of sediment. Thought Mr. Allardt's estimates of solid matter, and amount of water passing the railroad bridge, wrong. Prof. Thos. Price, chemist and engineer, estimated the total yield of gold, since 1849, at $1,200,000,000. During late years, the yield has been about 19,000,000 annually. Hydraulic mines would produce about $14,000,000 this year. Witness said there was no poison contained in the debris on Bear river lands, and thought the water flowing there was good for irrigating land. Had visited the land of plaintiff, and saw no signs of vegetation having been poisoned. He believed hydraulic mining had been profitable, but some claims had not paid yet, owing to the great expense in opening them.

A. F. Williams, of Oakland, had been engaged in mining about 27 years. He visited the land owned by plaintiff in September, 1876, and twice within the past month. He went to view the land and crops. Several gentlemen were with him. At his last visit did not notice much difference between the condition of the land in 1876 and now. Several points on the land were designated by witness, where they had dug down and measured the sediment, which he stated to be from three inches to one and one-half or two feet in depth. He couldnot see any material difference in the growth of weeds on the land covered by sediment and that not covered. On ground covered the deepest with sediment, they saw a light crop of barley. In a field, south and west of Keyes' house, he found a crop of corn growing on ground covered with sediment about one foot deep. There were many well-defined ears on the stalks. The corn was here produced and shown to the court; one stalk was measured, and found to be nine feet six inches long, and the ears, two in number, had the appearance of well-defined ears in the milk. Witness said these specimens were a fair sample of the corn in that field. He went up to the bridge, and saw a field of corn there, on ground that was covered with sediment, about three feet deep. That corn was as good as any he had seen. He thought that if the mines were stopped, the debris would continue to flow. He said if the mines continued work, the dams or dumps would be increased in size, and afford more protection by keeping the tailings back. Witness, on cross-examination, said he owned interests in several hydraulic mines—one located at Smartsville. Said he did not think the mine was filling up the river, but some fine sediment might come down this far. He had not furnished witnesses money in this case, and he came as a witness by subpœna. He did not go down to Keyes' land, last Sunday, to make his damages look light. He went to gain information, and see the growing crops, that he could testify intelligently.

Wm. Campbell, of Lake Tahoe, formerly resident of Bear river, near Johnson's crossing, visited the land of plaintiff, last Sunday. The land was covered by sediment, to the depth of 12 to 18 inches. Saw growing crops on this sedimentary land. Did not see any grain or corn growing on other than sedimentary land. He considered the corn, potato, and bean crops good. The corn here exhibited is a fair sample. Had not seen any that looked better. Considered the land worth double now, for growing corn, potatoes, and beans, which it was before being covered with sediment. Did not know if it was any better for small grain or not. The corn, potatoes, beans, and fruit, growing there, were as good as in other places. He saw a field of corn, just up, which looked well. Did not think a man would plant crops, knowing it would not produce.

W. A. Findley, David N. Jones, J. W. Laymance, E. J. Tompkins, Josiah Dodge, Joseph Perrine, George W. Smith, Lewis Posey, A. M. Pitts and James McCarger, all gave testimony pointing strongly to the fact that land was improved rather than injured by the sediment.

J. P. Pierce, of Santa Clara, had formerly lived at Smartsville about nine years. Witness said the hydraulic mines at Smartsville had averaged from $50,000 to $300,000 per acre. There were about 2,000 inhabitants at these and vicinity, who depended upon the work and product of the mines for a living. The yield of gold at these mines, Smartsville and Timbuctoo, had been as much as $12,000,000, and they were no more than half worked out now. Witness said his company at Smartsville was a member of the organization to contest this suit, and had paid an assessment of $1,300 to the President of the organization. The assessment was levied on the assessed valuation of their property.

He gave a description of their ditch and mines at Smartsville and their farm of 1,700 acres near there, and said they irrigated about 300 acres of it with water from their ditch. It would not pay to work their claims by drifting.

Jasper N. Muns and L. Harding testified to the usefulness of sediment on farm lands.

A. B. Brady, among other things, said that to stop mining in Nevada county would almost entirely desolate the present thriving towns.

James O'Brien, miner and farmer, testified that he was a member of the Hydraulic Miners' Association, formed two years ago. His company paid money to the Association. Over 100 claims paid in the same way. He did not consider the fund a means for corruption, but for mutual protection. Ground that gave but two cents per cubic yard had been worked by him on a paying basis. His income from his hydraulic claims had been as much as $30,000 per annum.

Richard Abby, President of the Spring Valley Water and Mining Company, testified:

They had 110 men employed in various ways. He gave the working expenses of their mines, yield of gold, amount paid in by stockholders, and said they had declared one dividend of $200,000, and had declared one this year of $60,000. Could not say how much had been declared in all dividends. Witness said he was a stockholder in the Milton mine, located on San Joaquin ridge. That mine had also declared large dividends.

T. W. Balch, the next witness, said he was the owner of the Little York mining claims. Bought them from an English company over one year ago. Said in working all their claims they dumped the tailings on land owned by them. When he came in possession of them, most of the top dirt had been washed off. On cross-question, he said he paid $100,000 for the claims.

A large number of deeds and patents to land and claims were put in evidence.

Geo. S. Powell, Superintendent of the Bird's-eye claims, estimated the gold taken out of these claims at between $30,000,000 and $40,000,000. The balance of his evidence was corroborative.

The evidence of Wm. Roblin, J. L. Gould, Hiram Searls, Thomas Patterson, and of two mining engineers, E. C. Wren and Natono Westcoatt, was mainly corroborative. The last-named said that 20,000 acres was the most that could be overflowed under any circumstances in Bear River valley. Said the farming population of the valley was no more than 75 or 100. Was of the opinion that a good system of levees would protect the land at all times.

August 9th the defendants closed their evidence.

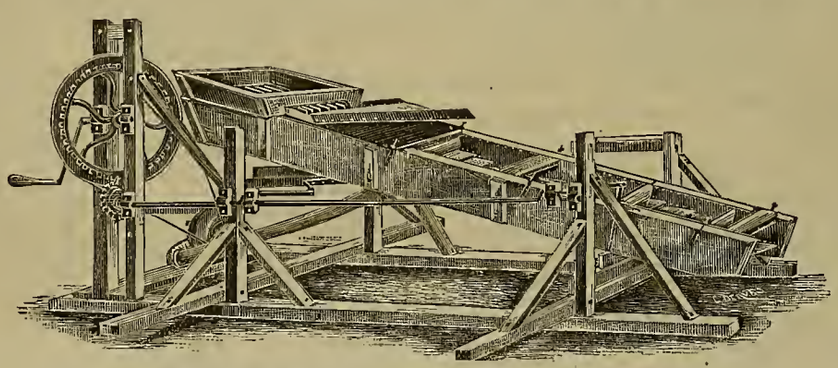
Joseph Johnson, S. D. Woods, Frank Kirshner, B. F. Dam, W. L. Ousley, B. D. Gray, David Hevilbart, A. K. Baker and J. D. Lewis were called by plaintiffs to give rebuttal testimony, most of it concerning the effects of debris on farming lands.

Thomas B. Brewer and J. H. Keyes were each recalled to correct some points in their previous evidence, when counsel for plaintiff said their evidence was all in.

Judge Keyser adjourned the Court for the term. The evidence is to be printed. In about 60 days from adjournment the case will be argued.

The Russel Patent Amalgamator and Gold Saver.

We give an illustration of the machine which is at present at work on the auriferous sands of the ocean beach at the "Combination" claim. It was invented by E. F. Russel, an old and experienced miner of this city, and interested parties have a good opportunity of seeing it in practical operation.



RUSSEL'S PATENT AMALGAMATOR AND GOLD SAVER.

The operation will, with the aid of the cut, be evident. It consists of a sluice about 10 feet long and two feet wide. It is fed by a hopper, at whose bottom is either a bar or perforated iron screen, according to the nature of the ore worked, *i. e.*, gravel or sand. At present the perforated screen is in operation. By an inclined sluice at the bottom of the hopper, the coarse material, containing no gold, is discharged to the side of the machine, and so does not enter the amalgamating sluice.

The sluice proper is divided into four compartments, each of which has a fall of one inch to the foot. At about the middle of each compartment are placed three riffles, which are formed by indenting the copper plate with which the sluice is lined to the depth of about an inch, forming three troughs in the form of horizontal, triangular prisms, whose bottoms slide backwards and thus have a tendency to retain gold contained in the sand which passes into them. At the edge of each of these compartments or inclined planes, is placed a trough which contains quicksilver at the bottom. The quicksilver is protected by a grating of stout iron wire from the action of pebbles, etc., which would carry it off mechanically if this were not done. Hanging from a stout iron wire over the little stream which dashes over the edge of the compartment, is a curved plate of amalgamated copper, which sweeps the surface of the water, and is intended to save the "float gold," which would otherwise be lost. That it performs its office at the beach the amalgam which adheres to it proves beyond doubt. The whole sluice rests upon a pair of sliding bars, and is given an oscillating motion similar to that which the miner gives to his "pan," by means of a system of cranks and levers put in motion by a system of cog wheels and crank handle, as shown in the figure. The machine is so arranged that this motion may be imparted either by hand, by steam, horse or water power, or, as they are talking of doing at the beach, by means of a windmill. The whole sluice, it is necessary to add, is lined by amalgamated copper plates, so that wherever the gold lodges it will be attacked and retained. The inventor claims that with two (miner's) inches of water, he can put through 30 tons of ore in 24 hours.

The peculiar advantages claimed for the machine are, first, the small amount of water with which it can be run. It is claimed that with the same amount of water it will put through four times as much sand as any other machine. Second, the reciprocating motion is a great advantage, as it causes such an agitation of the material as is favorable to the settling and amalgamation of the gold. Third, the shape of the riffles, which is favorable to the retention of the gold. Fourth, the grating over the mercury boxes, which prevents the "flouring" and consequent loss of mercury. Fifth, the hanging plates to catch the "float gold." Sixth, the formation of compartments, which allows the fall of material in a sheet upon the amalgamated copper plates, which is also favorable to amalgamation. There are in all 21 receptacles for quicksilver, besides the hanging plates.

The machine, as we just stated, is in operation at present on the "Combination" claim, and seems to give satisfaction to all parties concerned, although working with a bad supply of water. The results of the clean-up are awaited with some curiosity by all concerned. We can recommend this machine as worthy the investigation of all interested in placer mining, as it evidently combines the advantages of most of the methods hitherto in use. It can be seen at work upon the beach, or at the office of the agents, Kluit & Morizio, room 24, Safe Deposit Building, S. F.

Edison Again.—Edison has ascertained that electric and magnetic currents are stronger where a lode exists than where nothing but country rock abounds, and where the ore body is large and rich they are found to be the strongest and to vary with the size and richness of the vein. He is confident that he can manufacture instruments with which, by careful experiments and after minute comparison of results, he can tell not only the richness and extent of ore bodies beneath the surface in fissure veins, but also the kind of metal which they contain. The Gold Hill *News* is our authority for the above.

Oil Well Packer.—James C. Thompson, of Barnhart's Mills, Pa., has patented an improved vacuum packer for oil wells, for shutting off communication between the upper strata of rock and the oil-bearing rock, and it consists of three apertured metallic disks placed on the well tubing, and arranged to receive the vacuum tube, which, by its weight, compresses a rubber packing disk vertically, so as to expand it laterally to fill the bore of the well.

The subject of building a narrow-gauge railroad from Virginia City to Reno is being again agitated. Surveys show that that town can be reached in 30 miles by a practical route.

Another giant powder cap has been played with, and another victim is the result; this time a boy about six years old; wounded in the breast, perhaps fatally.

Rook sharps from that vicinity pronounce the Bodie the richest gold mine in the world. It has a vein five inches wide which is nearly solid gold.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds

The Wood-Gas Process.

An Open Letter to Mr. ' « '.

Dear Sir:—In the course of a conversation with our mutual friend, Mr. ——, we discussed some points which are likely to interest yourself. Our topics were the general character of the wood-gas process, the construction and manipulation of wood-gas apparatus; the illuminating qualities of the product, the cost of its manufacture; and, finally, its special advantages in cities which, like your own, are far removed from English, North American, and Australian collieries.

In alluding to these points, it is neither necessary nor appropriate to adopt the abstruse form of a purely technical essay; but every salient consideration, whether technical or commonplace, which should be regarded by those who seek an advantageous investment, will give tone to what I aim to make a truthful and intelligible abstract of ascertained facts.

Prof. Pettenkofer first proposed wood gas as a means of illumination in the year 1848. To Mr. L. A. Riedinger, however, is due so many improvements in this valuable industry, that he is fairly entitled to divide its honors with the original discoverer.

Among the European towns lighted with wood gas are Bayreuth, Coburg, Wurtzburg, Darmstadt, Kempten, Regensburg, Aarau, Landshut, Zurich, Giessen, St. Gallen, Ulm, Erlangen, Luzerne, Salzburg, Innspruck, Chur, Passau, Rentlingen, Heilbronn, Trient, Solothurn, Augshurg, Munich, etc. In some of these, the product was enriched by gas from hoghead shale, grease, etc.; while in others the quality of unenriched gas from the firs of the great forest of Hagenau, was found satisfactory to the consumer. About 1854, Mr. J. C. Cresson, the engineer of the Philadelphia Gas Works, had his attention called to the subject by one Breisach, who was familiar with the German practice.

In Mr. Cresson's annual report for 1854, to the managers of the Philadelphia Gas Trust, he states, "as a matter of official record, that a cord of ordinary fire wood will furnish nearly twice as much illuminating material as is obtained from the best Pittsburg coal." This year he carbonized 50 cords of wood.

In his next report, for 1855, he reports 830 cords of wood as carbonized during the year, and gives the yield of first-rate gas per cord of 128 cubic feet, at 12,000 cubic feet from common shore pine; and 15,000 cubic feet from dry oak. During 1856, 644 cords of wood were carbonized.

The subsequent abandonment of this mode of lighting, arose solely from a development of the Pennsylvania collieries and coal transport, which largely cheapened the cost of bituminous coals, as laid down in his sheds, and rendered them a cheaper gas material than the various woods.

Just before the war of the Rebellion, several of the southern cities of the United States were lighted with wood gas; among them, Wilmington, N. C.; Charleston, S. C.; and Macon, Columbus, and Augusta, Ga.

I was, at the time, engineer of the Savannah, Ga., gas works, making about 100,000 cubic feet per day, from the coking coals of Lancashire, England, from which we were soon afterward deharred, by blockade of our port.

I at once adopted the more appropriate iron retorts, made the requisite changes in the ovens, and supplied this town, of 40,000 souls, during four years, with a wood gas, whose mellow splendor elicited the approval of the consumer; while its economy of manufacture sustained satisfactory dividends throughout those terrible years, and won me election to a directorship in the Savannah Gas Light company.

Apart from the experience thus obtained, in the manufacture of some 125,000,000 cubic feet of wood gas, I have since translated or collated the whole German practice, and built wood gas works at Red Bluff, Reno, and elsewhere.

You will see, from this necessary personal mention, that I advise you to adopt a mode of lighting with which I am familiar from individual practice, as well as from the comparison of the labors of others.

I.—General Character of the Process.

Generally speaking, the illuminating gases from wood and coal are similarly produced, each material being distilled, or carbonized, in close vessels called "retorts," which are brought to the required high temperature by the application of heat, which is afforded by a furnace exterior to the retorts, and transmitted through their enclosure to the material within.

The tarry vapors, oily products and acids of the crude wood gas are next separated, partly by cooling impact and washing, and finally by the chemical affinity existing between the hydrate of lime and that master-enemy of the illuminating value of wood gas, carbonic acid. Thus deprived of its entangled impurities, the gas is measured and stored, and ready for distribution to the public and private lights.

II.—Construction and Manipulation of Apparatus.

While the process is, as has been observed, substantially the same in both cases, wood gas demands a different proportioning of what apparatus it borrows from the coal gas manufacture, and certain appliances exclusively its own. Of the latter class is the "dry-room," wherein even freshly-felled wood may be brought to a state of perfect dryness. This feature, though absolutely unrecognized in the United States, and infrequent even in Germany, is necessary to a well-ordered gas-work.

No air-drying can satisfactorily strip the wood of moisture, the presence of which acts to chill the retorts below a proper temperature, to reduce both the volume and value of the gas product, to increase the quantity of lime required to remove carbonic acid, and to add 20% to the labor of the stoker, by compelling him to handle this proportionate weight of useless and obstructing water.

The wood is therefore prepared for the retorts, through the agency of the waste heat of the furnaces, hy drying for many hours at a temperature ranging from 150° to 200° Fahr., 60° to 95° centigrade.

Brought, then, in say 24 hours, to a state of dryness which even years of mere atmospheric exposure would fail to entirely effect, the wood is ready for the retort, which is a semi-cylindrical vessel with a length of four or five times its diameter, and is kept at a cherry-red heat.

After the wood is introduced, the retort-lid is luted on, and the evolution of gas instantly begins, with a speed almost like that of an explosion at first, which rapidly diminishes to the close of the charge.

Well-dried wood requires 60 minutes to work off, while damp wood is but imperfectly distilled in 80 minutes. The gases, vapors and entangled liquids which rush from the retort to and through the hydraulic main, are composed of some 50 different compounds of the original elements of the wood, as hydrogen, oxygen, nitrogen and carbon, the chemical names of which are only of interest to the laboratory student.

Popularly, then, we may call crude wood gas a mixture of

a. Wood tar	}	Liquids and
b. Wood vinegar	}	Vapors.
c. Carbonic acid	}	Gases.
d. Carburetted hydrogen	}	

Of these, we arrest the first three; and measure, store and apply the useful fourth.

After all the stress of drying, much steam is evolved from the union within the retort, of elementary oxygen and hydrogen: the water which results, dissolving the acetic acid and constituting its dilute form, wood vinegar.

Passing through the coolers, or so-called "condensers," the gas surrenders at its lowered temperature most of the tar and wood vinegar, which escape, through suitable overflows, to special receptacles.

These condensers are variously constructed:

1. As vertical tubes, radiating in air or in water.

2. As horizontal tubes, radiating in air or in water.

3. As "ventilating" or "flue" condensers, of the Kirkham and Wright system.

Vertical immersed tubes are preferable, where water is plentiful and cheap; otherwise, the "ventilating" type should be adopted.

The neophyte might suppose that this more cooling to atmospheric temperature would deposit *all* the liquid matter; but as an important and, until very recently, troublesome fact, much of it remains suspended as minute bubbles of which the pellicle is a liquid film, and the contents a true gas.

Halley's theory of this "vesicular" form of vapors, has led to the invention of the Pelouze and Audouin condenser, which discharges a multitude of fine jets against opposed surfaces, and thus ruptures the enclosure, just as we crush the shell of an egg when we throw it against a wall.

Certain mechanical features of my own have improved this beautifully philosophical instrument; and, after treatment hy it, vapors cannot exist at any temperature which is lower than the boiling points of the liquids which partially compose them. The indifference of the Californian quicksilver producers to the merits of this machine is unaccountable.

Having thus condensed the gas, first, hy simple cooling, and, second, hy mechanical impact, we proceed to take out any finely-divided wood ash which may have been carried over, the rest of the acetic acid, and some portion of the carbonic acid, in a capacious vertical cylinder known as the "scrubber."

In this vessel the gas passes upward to meet a downward flow of water, which eufilms the coke or twigs with which the scrubber is loaded from top to bottom.

The only impurity now remaining is carbonic acid, formed in the retort by the combination of part of the oxygen with part of the carbon of the original wood. But for its destructive effects upon the light-giving constituents, carbonic acid might be ignored by you, as it is, really, in many towns; but in your case, the lime necessary to arrest it costs less than the enricher necessary to counterbalance its destruction of light, and you must therefore use a set of lime-purifiers.

These are boxes of cast-iron, though purifiers of masonry or of wood are also used, carrying the hydrate of lime upon slotted trays of wood, and provided with movable sheet-iron covers, which enter a hydraulic joint.

I propose to give you three of these purifiers, each of which is seven feet square, and contains six horizontal tiers of the slotted lime trays.

These are connected to a rotary center valve, so chambered that two purifiers shall always be at work, and one out of action for recharging with lime. Each working box, then, contains about 300 square feet of trays, which will jointly receive the hydrate from 1,500 pounds of quicklime, equal to the thorough purification of about 40,000 cubic feet of gas.

The gas is now completed, and it only remains to measure it hy an ordinary station meter, and store it in the gasholder ready for sale.

The manipulation of the apparatus is so simple, that any one of average muscle and brain can attend to it after a few days' instruction.

The fires are to be carefully attended to. A given weight of dried wood is to be placed in the retorts 16 times during each complete day of 24 hours. The overflows, gauges and valves are to be kept clean, and a fresh charge of lime is to be turned to work as soon as the lime-water test shows that the gas begins to be a little foul at the outlet of the purifiers. These duties are simple enough on paper, but simpler still in the daily routine of work. It may be observed that the corrosive acids held in the crude gas are so diluted hy the attendant water, that the apparatus, other than the retorts and their settings, is next to imperishable; while the completed gas is almost perfectly neutral. One of the large retorts I propose will make 20,000 cubic feet of gas per day during its "lifetime" of 300 working days.

III.—Illuminating Value.

German experimenters say that wood gas gives one-fifth more light than coal gas, while Mr. Cresson says it is one-half better. Both these overstate the value of wood gas, or, at any rate, of the gas from such wood as you can procure.

As a fact, wood gas varies in quality according to the following conditions: The quality of the wood; the dryness of the wood; the character of the apparatus; the heat of the retorts.

The poorest wood gives say 10,000 cubic feet of 10-candle gas, per cord. Your wood, which is described as similar to our ash, will give 15,000 cubic feet of 12-candle gas.

The pitch pine of our Sierra Nevada gives 22,000 cubic feet of 18-candle gas; while the unequalled "light wood" of our southern Atlantic seaboard yields the great volume of 28,000 cubic feet, also, of 18-candle gas.

The residuary charcoal varies from 450 to 600 pounds per cord distilled, and is applied in conjunction with supplementary wood, as fuel to heat the retorts.

As a 12-candle gas is not likely to satisfy your consumers, some enricher must he added; and the most appropriate material will be the celebrated "Hartley shale" from Australia, 10% by weight of which will bring your cord yield up to 16,500 cubic feet of 18-candle gas.

IV.—Cost of Manufacture.

In calculating this subject, I have, after consultation with your associate here, taken the elements of cost at the following figures:

1. Gas sold per day (cubic feet)	18,000
2. Cost of wood used in retorts (per cord)	$5.00
3. Cost of wood used as supplementary fuel (per cord)	$0.60
4. Cost of lime for purification (per 100 pounds)	$1.00
5. Laborers' wages (per day)	$1.00
6. Manager's salary (per month)	$200.00
7. Superintendent's salary (per month)	$250.00
8. Cost of shale (per 100 pounds)	$3.25

Forty pounds of lime purify 1,000 cubic feet of gas; one cord of wood and 250 pounds of shale produce 16,500 cubic feet of gas; street leakage, 10%. One cord of wood is required as extra fuel for each two cords worked off in the retorts.

From these data we obtain

Monthly Cost of Manufacture—600,000 Cubic feet of 18-Candle Gas.

36 and 4-11 cords of wood in retorts, @$5	$ 218.18
9,091 lbs Hartley shale, @3½c	205.46
18 and 2-11 cords of wood in furnaces, @$6	109.09
24,000 lbs lime, @1c	240.00
120 days labor, @$1	120.00
Wear and tear	75.00
Clerk and Collector	100.00
Superintendent	200.00
Total, equal to $2.18 per 1,000 cubic feet,	$1,307.73

You may consider the allowances for salaries and incidentals too large; in which case you will, of course, do better than stated. In this, and every other estimate, you will find that I err on the safe side. If, then, you sell gas at $6 per 1,000 cubic feet, you will nett $1,900 per month; if at $6.50, $2,200; if at $7, nearly $2,500.

In other words, heavy as your investment is, it cannot fail to he largely remunerative, apart from the great economy, convenience, safety, and luxury which the municipality will reap as the result of your activity and enterprise. A sum equal to the city's present expenditure for coal oil, will make their streets, squares and public institutions one blaze of light.

V.—Local Advantages.

These are so manifest and important, that I need do no more than allude to them.

Beyond the cost of, say, 50 tons of shale, and of a couple of retorts with their appropriate fire goods, the current expenses of a year will circulate in the immediate neighborhood of your city, instead of being squandered among foreign collieries.

Your wood gas will carry none of that obstinate bisulphide of carbon which, it is stated, has enured to the injury of valuable hooks, archives and paintings in England.

Should your port of entry ever be blockaded, your home woods will still keep up an ample supply of tolerable gas to both public and private consumers.

The thousand and one technical arguments in favor of your adoption of wood gas, induce me, finally and as the result of over 25 years' labor, to assure you that it is, beyond all comparison, your most available method, from its superior compactness, simplicity, ease of management and certainly of results. It is, in your city, an untried one; but its calm and smokeless brilliancy is delighting a hundred other towns, and it has, therefore, passed entirely out of the catalogue of experiments. Coal gas answers your purpose as well, apart from the vital objection that its cost of production is considerably greater.

Respectfully, J. R. Smedberg,
Gas Engineer.

127 Beale street, S. F., Aug. 7th, 1878.

Forestry.—The Value of Catalpa.

Editors Press:—The testimony is cumulative, and comes from every quarter, as to the urgency that exists for the planting of forests in the United States to repair the waste occasioned hy reckless destruction, so as to provide timber for the inevitable wants of the future. Congress has appointed a commission, of which F. B. Hough, of Lowville, New York, is Chairman, to report on the whole subject of forests and forestry, timber demand and supply, and and its relations to the industries of the Nation. This is only following in the steps of older governments, where this important subject has been assiduously studied for generations. But the genius of Americans does not lead them to depend on governmental promptings and leadership, they being competent to project and carry out in their personal or co-operative capacity enterprises of the greatest moment.

Thus we have already many examples of individuals engaged in extensive tree planting, notable among which is that of the Messrs Landreth (the seedsmen of cosmopolitan fame), of Bristol, Pennsylvania, who already have 5,000 acres on the Rappahanock appropriated to this industry. Scores of Californians have devoted large areas to the growth of the eucalyptus. The transcontinental railways have also given attention to this subject, some of them appointing foresters and promoting sylvi-culture along their lines.

The veteran car-builder, Mr. E. E. Barney, of Dayton, Ohio, has done a good service to the country hy collecting and publishing facts as to the great value of the catalpa tree (*C. Bignonioides* and the importance of its extensive cultivation in groves.

Some of the facts he presents are truly startling. Thus, he says: "There cannot he less than 200,000,000 ties in the various railroads in the United States. At 200 ties per acre, it has required 1,000,000 acres of well-timbered land to furnish them. As the average life of ties is hardly more than five years, it requires 200,000 acres of land each year to keep up the supply. Three times that amount is required each year to furnish the lumber used in bridges and rolling stock. So that the lumber on 1,000,000 acres of land is required every year to supply the wants of our railroads for all purposes.

"Samples of catalpa, taken at random, indicate that this wood will hear the pressure to which it is subjected when used as railroad ties. Two catalpa railroad ties have been in use near our office over four years, and 12 others for the last five months. All hold their spikes well and show no indication of mashing more than the oak on each side of them, and over both of which heavily-loaded trains pass almost hourly.

"A catalpa gate-post was cut for fire wood and found in fair condition after doing service for nearly a century. Col. Cockrum has known it in use, without stain of decay, for fifty years."

The rapidity of the growth of catalpa in youth is astonishing, and it seems to grow equally well in any soil. It will grow from Iowa in the north to Florida in the south. The propagation is very simple: by scattering the seed on land either recently cleared or only partially so: or by raising the plants in a seed bed and setting them out. Catalpa also takes a fine polish and is an admirable ornamental cabinet wood. It is quite time that farmers should he wise enough to plant trees, not only enough for their own needs and that of their less provident neighbors, but also to supply the wants of our numerous railroads.

As one method of promoting timber culture, I suggest the formation of

Forest Corporations.

As it requires more than the average life of a man, beginning, say, at 25 years old, to harvest a timber crop from his own planting of seed, it would seem best for this work to be done by forest corporations. In every neighborhood, men could readily select areas suitable for planting groves and obtain them at minimum prices. They could also procure labor from the members of the corporation, at the lowest rates, to attend to the culture of the trees. Another advantage of having such an enterprise carried on by distant capitalists would be that the sympathies and interests of the vicinage would he concentrated upon it, which would not he so likely to be the case if it was undertaken by foreign or absentee parties, who, also, would have to pay, perhaps, double prices for the necessary labor, while nine-tenths

(Continued on page 102.)

MECHANICAL PROGRESS.

The Introduction of Steam Wagons.

Steam wagons seem to be gaining entrance on this coast. One of English manufacture is being used for threshing by H. C. Copeland, of Tehama county. It drives the separator, and, at time of moving, it draws all its wagons and machines, and other appurtenances any distance at a speed of about three miles an hour, its weight being about six and one-half tons. Its work seems to be generally satisfactory.

Another enterprise, of more strictly local moment, is being pushed by Gaskill Bros., of Campo, San Diego county. From an account in the *Arizona Sentinel*, we learn that the contract for carrying the daily mail between Yuma and San Diego has been intrusted to Gaskill Bros. About 100 miles of the road lies across the California desert. Across this stretch, mail and passengers are soon to be carried by steam. Messrs. Gaskill are industrious inventors, and have obtained a number of patents. One of their last inventions is a steam wagon, designed more particularly for traveling level and sandy roads. A working model has been made which fully demonstrates the practical value of the invention. One of the brothers has just purchased a suitable engine and boiler at San Francisco, of about two-horse power. The wagon will be made in their shop at Campo. It will have two driving wheels of seven feet diameter and 12 inches width of tire. The whole apparatus will weigh about 2,000 pounds, when supplied with fuel and water, and ready for business. It is intended to make an average speed of eight or ten miles per hour, carrying five or six persons and a moderate weight of baggage and mails. It will consume about 10 gallons of water per hour. There is plenty of fuel in the mesquit groves on the desert, and among the willows and cottonwoods on New river and the Colorado. One man can manage the whole thing. Messrs. Gaskill propose to have the new machine making regular trips across the desert by October 1st.

A LARGE CALIFORNIA THRESHER.—We learn from the Guadalupe *Telegraph*, that a grain separator, of unusual size, has been constructed upon the ranch of E. J. Preston, under his personal supervision, and from plans and ideas of his own; and the thorough and accurate manner in which each part performs its work, fully justifies the pride which the owner feels in his huge pet. It is called the "Red Elephant," from its size and color. The cylinder of this mammoth machine weighs 500 pounds, is 44 inches in length, has 12 bars, and 222 teeth; the shoe and the carrier are five feet in width, the axles, over eight feet in length, from wheel to wheel, and the box sets up high enough from the ground to obviate the necessity of digging holes for the sacks. The straw is furnished to the machine by two large derrick-forks, which lift half a ton at a time each on to the table, where four men fork it along, a few feet, to the self-feeder, which carries it into the massive jaws of the cylinder, in a constant stream, thus saving the labor and expense of several men, and working up a "setting" in half of the time occupied by other machines. The average capacity of the "Elephant," in good, fair working grain, is 2,000 sacks a day. It is run by a 16-horse power wood-burning engine.

A SIMPLE ELECTRIC LAMP.—We learn from *Seward's Journal* that M. de Parville writes enthusiastically of M. Reyner's new electric lamp, which seems to be as easily managed as an ordinary oil lamp. A rod of carbon, from 20 to 30 centimetres long and from one to two millimetres thick, is held at one end by a metal rod which tends to descend by its own weight, and at the other by a carbon wheel in a vertical position. The carbon is pressed strongly against the wheel, which is made to revolve slowly. A current of electricity from a battery of from four to six of Bunsen elements raises the carbon to a white heat at the point of contact of the rod with the wheel. A splendid light is produced. If a high degree of luminosity is required, the heated portion of the carbon may be increased at pleasure. Break the current and the lamp is extinguished. Restore the connection by turning a knob and the light flashes forth. The battery may be stowed away anywhere, and any one can use this illuminating contrivance in a house or workshop, without being annoyed with the difficulty and expense of maintaining any magnetic electric machine or steam engine.

STEAM CRANE.—A satisfactory public trial of a large steam crane, built at the steam crane works, Rodley, near Leeds, England, has been made at the quarries of Mr. Bradley, Meanwood. The crane is made to hoist, propel and revolve, simultaneously or separately, as desired; thus, a stone can be hoisted out of the quarry, and, at the same time traveled to any position required.

RINGING ENGINE-BELLS BY STEAM.—There are about half a dozen engine-bells on the line of the Pennsylvania railroad that are rung by steam. An iron rod is run from the bell to the boiler, and is turned on the same principle as the air-pump. when it is necessary that the bell should be rang, and the steam works the rod to and fro.

Compressed Air for Car Driving.

The use of compressed air for a motive power in street cars, is still being tested by experiments. We read in an Eastern exchange that a New Haven company has brought out an air car, the tubes of which are only eight inches in diameter. It is asserted that they withstood a pressure of 3,000 pounds to the square inch. This car has been tested a great many times during the past three months. On the last trip it ran to Whiteville and back, five miles, and had 650 pounds to the square inch left, air enough to have gone over the same route again. Freezing is prevented by a small air pump, which, from time to time, generates hot air, forces it to surround the cylinders, and thereby prevents any accumulation of frost. The car, it is said, can be managed by a boy, and from either platform. It makes no noise, and, as no machinery is seen, it resembles, in every way, an ordinary street car.

The *Railroad Gazette* says that it is the intention of the Second Avenue railroad company, of New York city, to place upon its tracks, cars propelled by air pressure. The experiment was recently tried, and proved eminently satisfactory. It is claimed for the new apparatus that the time may be reduced one-half, and that it can be worked at least 30% cheaper than horse cars, while noise, to a great extent, is avoided. The principle upon which the system is based, is that atmospheric air compressed into a small compass gives a reservoir of energy representing the mechanical force used in compressing it. Two long compressed air receivers, made of steel, are to be placed under the seats, and six under the platforms. These eight are connected cylinders, placed in iron frames between the wheels of the car. They are also connected with an engine between the crank-axels and wheels. The air is forced into the receivers by a 500 horse-power engine. The liberation of this air in the engine under the car, will turn the wheels. The car will be allowed to run by its own momentum on down grades.

GLASS HARDENED BY COMPRESSION.—Some interesting experiments, says the *Iron Age*, were lately made by Mr. Frederick Siemens, before the Berlin Polytechnic Society, on the resistance of glass plates hardened by compression and cooled in water. Upon a hardened plate 8.4 inches square and 1.1 inches thick, supported at its four corners, a lead ball, weighing 8.8 pounds, was dropped from hights varying from 3.3 to 6.6 feet. The plate resisted the shocks and broke only when a hight of 15.7 feet was reached. Another hardened plate 4.7 inches thick was broken by a weight of 2.2 falling from a hight of 14.8 feet; a third one succumbed to the shock of a ball weighing 1.6 pounds, falling 11.6 feet, while the same weight, falling 2 feet, broke an ordinary plate of the same dimensions. The great difficulty of hardened glass—its tendency to break spontaneously—has been overcome by Mr. Siemens by placing the hardened cold plates in boiling water, and allowing them to cool very slowly.

IMPROVED FIRE BARS.—*Iron* tells of a new style of fire bar devised by an English inventor to secure fuller combustion of fuel. The peculiar feature of their bars is the shape of the spaces left for the air to pass through. These, instead of being straight, are of a wave-shaped form, the convex parts of one bar fitting into the concave parts of the adjoining one, and the proper distance being regulated by the width at the ends in the usual way. Additional oblong air-spaces are also provided, and placed in the spaces between the wave-shaped openings. The underside of the bars is made as thin as possible, so as to give the air ample inlet area; and when they have to be fitted against the sides of boiler-flues, a set of tooth-like projections is cast on to the edge of the outside bars. Any portion of the length of these teeth can easily be cut off by a hammer and chisel to effect the desired fit. By the use of these bars the inventor claims a large saving in fuel.

WHEELS AND AXLES.—At the Paris Exposition, are shown wheels made in cast iron, gun-metal or phosphor bronze, with patent adjustable nuts on the axles, by the use of which any slack can at once be taken up, and left-hand screws are rendered unnecessary. The spoke ends, instead of being driven endwise into the nave, are dovetail-shaped, and forced sideways into the similarly shaped recesses of the cast-iron naves, a plate on top of them, secured by bolts, keeping them in place. Instead of securing this plate by bolts and nuts, it is sometimes held up by a large nut screwed over the back oil-chamber, thus forming a very neat-looking nave.

ENGLISH CHIMES.—A fine carillon peal of bells, cast by Messrs. Gillet & Bland, Croydon, has been presented to St. Audrew's church, Plymouth, by Mr. C. Norrington. The *Western Daily Mercury* says the construction is an improved and patented one. There are 10 bells, on which are played 14 tunes, one each day, every four hours. At midnight, a self-shifting apparatus changes the tune. The tenor bell weighs 35 cwt. 14 lbs. The 14 tunes are arranged on two barrels, of seven tunes each. The barrels are changed once weekly. The hammers, which strike the bells, weigh from 38 to 72 lbs. each, and the weight giving the motive power to the carillons, is over eight cwt.

SCIENTIFIC PROGRESS.

The Formation of the Tulare Plains.

Mr. J. R. Scupham, scientific expert of the Central Pacific Railway Company, makes a report in the *Bulletin* on well-boring in the Tulare plains, which contains some interesting facts concerning formations, etc. The well was bored near Tipton. For a depth of 280 feet mountain debris was pierced. The first signs of an abundant supply of water were discovered after passing through a stratum of sandstone from four to six feet thick, lying over a bed of quicksand. The first flow was at the rate of eight gallons a minute from a seven-inch pipe one foot above the surface. Then a five-inch pipe was sunk 30 feet deeper, which pierced a stratum of blue clay containing four separate layers of sand, each of which contributed a supply of water. The lower one gave out a considerable volume of water. It was decided to stop sinking at this step to secure the water already discovered. The well at last accounts was delivering 86,000 gallons a day out of a five-inch pipe, four feet above the surface of the plain, and the supply is constantly increasing instead of diminishing.

Mr. Scupham reports that the water is remarkably pure, showing its identity with glacier lakes. It has less than six grains of solid matter to the gallon. The solid substance is chloride of sodium, which corresponds almost exactly with the waters of Lake Tahoe. A well of this capacity gives enough water to irrigate 100 acres of ground, and its cost is estimated at from $700 to $1.000. Mr. Scupham believed that water can be obtained throughout the whole length and breadth of the Tulare plains by sinking wells to the depth of 300 or 400 feet. As to the chance of diminished flow after numerous wells have been sunk, Mr. Scupham estimates that wells on each quarter section of land would not materially affect the supply, and they might be placed much closer together without decreasing the flow. The temperature of the water is 72°.

The Tulare plains are in full view of the Sierra Nevada, which rise from it somewhat abruptly. Mr. Scupham, John Muir and others, believe the debris to be the ruins of extinct glaciers, which eroded the Sierra to their present shape. Geologically speaking, this debris was carried at a very recent period from the mountain slopes and summits and deposited in the valley. Mr. Scupham thinks that the main portion of the Sierra was at one time more than 20,000 feet high, and the loftiest peaks were at least 5,000 feet higher. From the aerial currents from the west, heavily charged with moisture from the ocean, immense volumes of rain were condensed and precipitated on the mountain slopes toward the ocean, which, flowing to the plains, caused a great lake, which is now extinct.

A JAPANESE SALAMANDER.—The *Independent* notes that a fine specimen of the gigantic Japanese salamander (*Triton Sieboldii*), nearly three feet long, has been added to the Brighton aquarium. It is thoroughly acclimatized, existing in fresh water at a normal temperature and feeding principally on raw beef and liver, which it seems to prefer to the species of fresh water fishes offered alike for its acceptance. It is a sluggish, weak-limbed reptile, covered with a dark brown skin, the head and throat being thickly dotted with the glands so characteristic of the water newts, and the large pores serving to distribute the viscous matter shed over its exterior are distinctly visible. The mouth is remarkably capacious and the eye small and easily overlooked. Specimens were first brought to Europe by Dr. Von Siebold, who discovered them in a lake on the top of a basaltic mountain in Japan. It is the *Sieboldtia gigantea*, Bonaparte, and the *Salamandra maxima*, Schlegel, but is now referred to the genus *Cryptobranchus* (*C. Japonicus*, Van der Hœven). It is very closely allied to our American gigantic newt (Menepoma) of the Alleghany mountains, the difference being mainly in the gill-slits, which are permanent in the American form, but which disappear in the adult of the Japanese one. It is also interesting as being nearly allied to the huge fossil salamander (*Andrias Scheuchzeri*) from the fresh water Miocene beds of Œniugen, Switzerland, famous as the *Homo diluvii testis* of Scheuchzer, who long maintained it to be a fossil man, and, therefore, an indisputable relic of the Noachian deluge. Cuvier proved that it was merely a gigantic salamander.

NEW FOSSILS.—Prof. E. D. Cope, of Philadelphia, has recently described some reptiles, from the Permian formation, in which the humeri possess many of the characters of those of the mole and other fossorial *mammalia*, in the great development of the muscular insertions and epicondyles, and the presence of a supracondylar foramen. They are referred to five species of three genera of *Pelycosauria*, a tribe of the order *Rhynchocephalia*.

SIZE OF THE TIGER.—The size which the Bengal tiger reaches, is a matter of some discussion; but, in *Nature*, J. Fayrer mentions cases in which a tiger has reached the size of eleven feet nine inches, or even twelve feet, measured from the nose to the tip of the tail, before skinning. Still a tiger is large that reaches ten feet.

Expansion and Atomic Weights.

A German authority gives the following review of the expansion of the solid elements as a function of their atomic weights: Since all gases, under similar physical conditions, contain in equal volumes the same number of molecules, they must all have the same co-efficient of expansion, because this expansion represents simply an increase in the energy of the progressive motion of the molecules. For the non-gaseous elements, however, no such simple relation has been hitherto observed. Wiebe has thrown some light upon the subject, by studying the expansion-co-efficients of the solid elements in connection with their atomic weights. The quotient of the density of any such element, referred to water as unity, divided by its atomic weight, gives the space occupied by one atom of that element. If the ratio of this value to the co-efficient of expansion be obtained, some striking relations appear, as is shown in tabular form for 26 solid elements. In the first column the symbols are given, in the second the density, in the third the atomic weight, in the fourth the expansion-co-efficient expressed in parts in a hundred million at 40° C., and in the fifth the ratio of this to the quotient of the density divided by the atomic weight. The numbers in the fifth column then represent the absolute expansion of the atoms, or the co-efficients of expansion of the elements referred to their atomic volumes. These atomic co-efficients often show simple relations for closely allied elements; thus the value is the same for iron, cobalt, and nickel; the numbers for arsenic, antimony, and bismuth are as 1 : 3 : 4; those for zinc and cadmium as 2 : 3, etc. If these co-efficients be regarded from the standpoint of Lothar Meyer's law of the periodicity of the properties of the elements, and be graphically represented as a function of the atomic weight, they give a curve similar to that of the atomic volume, in which members of natural families have an analogous position. Hence the author concludes that the absolute expansion of the atom is a periodic function of its atomic weight.

THE MICROPHONE AND INSECT VOICES.—A writer in the *Entomologist's Monthly Magazine* suggests that, as the microscope reveals to the eye of man all the most insignificant of nature's works, why may not the microphone disclose to our hearing the most inaudible sound. Through Prof. Hughes's discovery, we may hope, he says, to have great light thrown upon the somewhat obscure subject of stridulation in insects. We do not see why the microphone may not be applied to detecting the high-pitched sounds produced by the grasshoppers and crickets, and the now inaudible stridulating noises made by moths and other insects. It could, possibly, be applied to studying and detecting the noises produced by fishes and marine invertebrate animals. It could also be applied, perhaps, to detecting the gnawing of museum pests in collections of stuffed mammals and birds and entomological collections. Particularly valuable would its use be in detecting the presence of white ants in the tropics, in the inside of articles of house furniture, which this insect ruins before its work is usually detected.

THE SMALLEST INSECT.—We read that Hon. J. D. Cox, who is an excellent microscopical observer, contributes to the *American Naturalist* an illustrated account of the smallest insect known (*Pteratomus Putnamii*), a parasite of an ichneumon, which attacks the common leaf-cutter bee, originally described by Packard, from an incomplete specimen. Mr. Cox gives a carefully-prepared figure of the perfect specimen which he discovered, and clears up some unknown points in its structure. This is a hymenopterous insect, with the wings long and narrow, linear and beautifully ciliated—not being fissured, as erroneously supposed by Packard. The winged atom is one-nineteenth of an inch long, and bears off the palm among all known insects for extreme exiguity.

A VOLCANO IN THE MOON.—Dr. Hermann J. Klein, of Koln, with his five and a half inch dialyte, by Ploesel, discovered, some time ago, on the moon's surface, a great black crater on the Maro Vaporum, and a little to the northwest of the well-known crater Hyginus. He describes the crater as being nearly as large as Hyginus, or about three miles in diameter, being deep and full of shadow, and as forming a conspicuous object on the dark gray Mare Vaporum. So far, the English observations of the new crater have been perfectly in accord with those of Dr. Klein, and if the existence of this new crater be confirmed, it will form the strongest possible evidence of a real change on the surface of the moon; a change, moreover, of a volcanic nature.

MR. BENNETT'S CHART.—A special chart of the Polar regions has been made in London for Mr. Bennett, whose expedition, next year, is to go to Behring's strait. The warm current flowing north through the strait is represented as sweeping round the northwest coast of America, one arm of it going north by the west side of Banks' Land to 80° north latitude. No doubt this is the direction which it is intended the expedition will take. Kellett Land, at the north entrance to the strait, is extended into a great broad island, by the east side of which this warm current is represented as flowing. If such land really exists, it will certainly form an excellent basis for further operations by sledge.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

Drytown.—*Dispatch*, Aug. 10: The mining outlook is very favorable, although there is a good deal of growling by mine owners and workingmen in consequence of the irregularity of the supply of water furnished by the Amador canal company. The quartz mills in this section are idle about half their time. The Gover may be shut down if water cannot be obtained more regularly. The Pennsylvania has had a clean-up that is thought to have exceeded expectations, but since that they have had scarcely any water, although the mine and mill are crowded full of better rock than was crushed during the last run. The Potosi mine, now called the California, is doing nothing at present, owing to some hitch among the members. This company has been putting in an air-compressor drill lately, the air to be compressed by water. When matters are satisfactorily arranged, they may yet have a good mine. The Centennial mine, on Dry creek, is looking well. A 20-stamp mill is about to be erected.

Items.—Work is progressing rapidly on the reservoir to be used by the Monte-Richard mining company, and it will be completed as soon as possible, which will be but a few days. The mines are reported to be looking well in the vicinity of the Pioneer mill, above Volcano, and there seems to be a new impetus given to the prospecting for quartz.

CALAVERAS.

Items.—*Chronicle*, Aug. 10: The gravel continues rich at W. W. Cook's Maison d'Sante. The Bonanza, Moser & Co., pays largely. Preparations are being made for a clean-up at Veith's mammoth hydraulic. The Duryea claim, in Chile gulch, is paying better than it has for years. There are drifters enough employed to keep the batteries at work night and day. As very few inches of water are sufficient to run the mill, the scarcity of that commodity will not affect this claim much. Brown & Co., located on Tunnel ridge, are pushing things. A good clean-up at the Rough Diamond is rumored. Everything runs smoothly at this mine. The pay chute was struck in the Sliter & Hoey claim, Old Woman's gulch, Tuesday last. It is expected that the necessary drifts will be run and the ground opened for breasting in a couple of weeks. The mill is in complete readiness to run, so that the claim will be the scene of busy operations in the course of a couple of weeks. The 1550 level in the Gwin mine has entered the pay chute to the north of the shaft. Stopes are to be opened immediately. The mills are still kept running on ore from the 1400 levels. The new mill on the Champion mine, at West Point, is approaching completion. At Mosquito everything is nearly in readiness for starting up the Banner. The hoisting works, pumps, engines, etc., are being repaired preparatory to taking out the water. Operations at the San Joaquin, Holmes, proprietor, are progressing favorably and steadily. At Sheep Ranch the Wallace & Ferguson is still proving itself one of the richest mines in the State.

EL DORADO.

An Amador Man's Notes.—Amador *Ledger*, Aug. 10: I have been traversing El Dorado county, and thinking the notes I have made may possibly be of some little interest to your readers I will place them before them. At Nashville I found that the Consolidated California company's mine had been jumped by a Mr. Curtis, he representing a company. The thing is at a standstill, but will retrieve itself under the auspices of the new company. The mines at Logtown are doing little or nothing, merely sinking shafts. I learn that the old Pocohontas will soon commence operations, a Burleigh drill having been received. Mud Springs is very prettily situated, but there is not much business transacted there. Placerville is very dull. Taking it all in all, El Dorado does not compare favorably with our own county. But little mining is going on along the Comumnes. The Phœnix, or rather Empire mine is not running to its full capacity, though 30 stamps are run by steam pressure, scarcity of water being the cause. The Pennsylvania is not running at the present writing; no water.

FRESNO.

Letter from Coarse Gold Gulch.—*Republican*, Aug. 10: One of the richest mines in the new district near the summit has recently been found by a party who left here some two weeks ago. The owners, Mike Baker, James Hansen, Harry Kirkwood and John Singo, give the following facts: The mine, which is located on this side of the county line of Fresno, is called the Eureka, and has a five-foot vein. The assays, by the local assayer in that district, gives it at $81.54, in silver, per ton, 62% in lead, which is supposed quite sufficient to run it through a smelting furnace. The assayer stated that it was the best vein as yet discovered in that section. This mine is on the north side of the San Joaquin, and known as Walker's sheep range (the ore is in soft blue slate) Lake District, Pine City, eight miles to post office. Mining in this vicinity is progressing slowly but surely. Texas Flat mine is being sunk at the rate of one foot per day in a shaft of 12x6 feet, with an increasing vein from the top, of two feet to four feet, at the depth of 40 feet. The indications of the ore to the prospectors are satisfactory, who are going on with it. Hill & Hutchings have started their crushing mill, which is located on an extension of the Texas Flat, and they seem to be doing well. The Confidence mine will start up soon again. Several parties are working on the Lady Heller mine, which was for a long time abandoned, but now shows good prospects. McKenzie & Rhule have commenced working on their Last Chance mine with fine prospects.

INYO.

Water for Belmont.—*Independent*, Aug. 3: The Emigrant company have purchased the pipes and machinery of the Cerro Gordo water works, now to be used in conveying water from a spring, also recently purchased, to the company's mill now being erected directly at the mines, the Cachus and Valentine. The pipes will pass within four or five miles of the Belmont mines, which can be supplied. The ores from Belmont can be taken to the Emigrant mill, after the construction of a mile or so of wagon road. On the whole, things look bright for Belmout and the Emigrant.

Rex Montes.—The five-stamp mill is waiting for the winze from tunnel No. 3 to reach the new tunnel No. 4. This connection may be made in a few days. The winze is in good ore almost all the way, and there is no doubt that the new tunnel will render available a large quantity of the same. It will probably require still another tunnel to determine anything very satisfactory as to the permanency of the mine.

Items.—A tunnel 105 feet long has tapped a very rich gold ledge in a mine called the Orion, located in Alahama district. The Independence tunnel will cut several fine ledges within the first 400 feet, and so on at short intervals clear to the Rex Montes series, less than 2,000 feet distant, and at a depth at that point of about 1,400 feet. A number of these ledges, known to be rich from surface prospects, belong to the tunnel company. Several adjoining claims, particularly two belonging to McDermott and others, are highly valued, one of them showing a rich ore vein three feet in width. As it is an established fact that the Potosi series, to be cut by this tunnel, yield ore of a very high grade, and that even back to the Mountain View, which crosses the very summit, the mines are at present almost inaccessible, the wisdom and necessity of the tunnel is too manifest to be gainsaid. M. J. Byrnes has just returned from San Francisco and gone over the Inyo range to his mines at Deep Springs. He is accompanied by a party who will examine the property with a view to purchase. The ledges are rich, the ore assaying from $200 to $800 per ton. The Hidalgo mining company, of Darwin, last week filed in the County Clerk's office its certificate of incorporation.

LOS ANGELES.

Black Star.—Santa Ana *Times:* In this mine there is a shaft sunk down about sixty-five feet, and in sinking this shaft two veins of excellent coal were discovered. The first vein is at a depth of about twenty-seven feet and is now being very actively worked. A tunnel is run in from the side of the hill, through which cars bring out the coal to the dump. Drifts or chambers run in nearly every direction from the main tunnel, and in about three weeks there will be work for about one hundred miners. Mr. Witte says that in about that time they would be able to take out one hundred tons of coal per day.

The coal of the Black Star Mine has been tried by a great many different parties and is pronounced to be equally as good an article as the Sidney or Seattle coal, and it can probably be put down in Los Angeles at least from two to five dollars per ton cheaper than either of the above-named.

The vein that they are now working is about three feet in thickness and the other vein is at least four and a half feet.

MONO.

Various Mines.—Bodie *Standard*, Aug. 7: Since last report work in the McClinton has progressed favorably in the north drift, and the distance advanced is 18 feet; total, 291 feet. Work has been stopped for the present in this drift, and sinking the shaft commenced. The shaft will be driven down 200 feet further. The main shaft of the Blackhawk has gained eight feet the past week, making a total depth of 356 feet. The ledge is improving in quality, though about the same width, the rock continues very hard. There are still three shifts at work. Still cribbing in the South Standard shaft, and very fair progress is being made. It will take nearly two weeks more to complete the contract. The hoisting works will reach here in a few days. The work of sinking the Goodshaw shaft has not been resumed as yet, but cribbing progresses finely. The whim which was ordered some time since will arrive Wednesday. Work has been resumed on the Wide Awake, and the main shaft has now attained a depth of 68 feet. The shaft will be driven down as rapidly as possible. The Owyhee prospects well; the progress made goes to show that the owners are determined to develop their mine, and show all it contains in a short time. Work on the Champion was resumed last week. The contract calls for sinking the shaft 300 feet. The force at work on the Paris is making fine headway. The drift is now in 62 feet, and the face looks well. The main incline in the Hayes has attained a depth of 85 feet, and the ledge is between three and four feet wide, and of good average ore. The Bulwer steps forward with rich developments. There is report of a rich body of ore being uncovered in the Belvidere. There are strata in the ledge of that mine which assay from $1,000 to $5,000. The Booker shows a fine four-foot vein, assays proving it to be rich in mineral. The Richer looks first-rate, and the best indications exist for opening up a rich ledge.

NEVADA.

Monthly Review.—Grass Valley *Union*, Aug. 6: The mining situation continues favorable, and for the month past some decided improvements are noticeable. The New York Hill mine, which has been in the dumps for a long time, has made a surprising and gratifying change by striking a new and very rich chute of ore at a low depth. The Centennial, which has shown itself to be a favorable prospect for a year or more, continues to develope richly, and gives promise of making a rich and reliable mine. The developments in the Alaska are also very encouraging. The improved prospects of these mines is consequent upon deeper sinking, and when a few months more have passed, in which time new levels will be opened, we will be enabled to make a gratifying exhibit of the new developments. Prospecting is being extensively carried on, and the custom mills are kept constantly busy with their stamps. Mill men say that it is a much more busy season with them than last year. As heretofore noticed, Osborn Hill and the country immediately south of Massachusetts Hill, are the present favorite prospecting fields. Both of these localities are literally seamed with quartz ledges, which are yet destined to yield enormous treasure when a well digested system of tunneling and drainage is perfected. Osborn Hill is so situated that it could be drained by a tunnel from the Frenchb Lead and above as far as Scadden's Flat, that would subserve a similar purpose of drainage for a system of ledges which have been very rich in the past. Co-operation, energy, and spirit are needed.

PLACER.

Items.—Dutch Flat *Forum*, August 10: Operations have been again commenced on the Lincoln coal mine. Quartz prospecting is reported to be lively in the vicinity of Auburn. Bell's mine at Auburn, the bonanza of Placer county, is still showing gold in abundance.

Cinnabar.—*Argus*, Aug. 10: A ledge of cinnabar is reported to have been discovered at the site of the 20-mile house, on the Auburn and Sacramento road, in this county. The Mayflower mine has at least two beds of gravel, one varying in thickness from eight inches to three feet, the other being about fourteen feet thick, and yielding an average of five to ten cents to the pan.

Yankee Jim's.—*Herald*, Aug. 10: There are some placer claims in the district that still pay, though for want of water none of them are worked at this season of the year. Some quartz ledges have been struck a short distance below town, and on these work is being prosecuted. The Live Oak, owned by the Gilbert Bros., has shown some fair prospects, and is being further developed. Another quartz ledge in the same vicinity, known as the Mastadon, owned by Messrs Tubbs, Durning & Mondoza, is being opened by running a tunnel into the ledge from the side hill. Another ledge, also in the same vicinity, known as the narrow gauge, and owned by Charles Trafton, is being prospected by means of a shaft sunk on the ledge. All these ledges are parallel to each other, and in the opinion of some they are separate seams of one grand mother ledge.

PLUMAS.

Bell's Bar.—*National*, Aug. 10: The company at work at this place have at last got their machinery on the ground and will soon have it running. They have a large boiler and engine, and a pump which is thought to be sufficient to handle all the water they will have to contend with, and more, too. The shaft is now about 90 feet in depth, and the indications were strong that it was about through the lava when the water drove out the workmen. We await developments by this company with some degree of anxiety, for if they get bed-rock it will show what the big blue gravel lead is worth.

The Jamison Shaft.—Work has again commenced on the big shaft in Jamison creek, the company having put up a pump which it is thought will manage the water. This is the third pump they have used. The chances are strong that they have a rich mine if they can only get to the bottom.

SIERRA.

Bunker Hill.—*Mountain Messenger*, Aug. 10: Bunker Hill mining company, near Brandy City, commenced sinking a shaft in their tunnel, 900 feet in, but were unable to go down more than 35 feet on account of water. They will have a meeting on the 17th, to take measures to go ahead, as they feel sure they have a good paying channel below them. When work was stopped the shaft was in a kind of blue gravel and cement, which was considered a good indication of a channel not far below.

Oriental.—The Oriental quartz company, near Alleghany, struck a ledge of very rich quartz last week. Upon examination and comparison, it was found to be identical with the rich quartz found in the North Fork mine, at Forest City. The ledge, so far as can be determined, is about five feet thick, and carries gold in about the same proportion as the North Fork. This will be encouraging to both companies, as it proves the existence of a permanent quartz deposit in the North Fork, which can be found by going down. The Empire claim, at Howland Flat, is worked out.

TUOLUMNE.

Harris Mine.—*Union Democrat*, Aug. 10: The new 10-stamp mill near this mine has just been completed. The capacity of the mill is 15 tons of ore in 24 hours. The mine has been worked by Mr. Harris the past four or five years. He went to work to see if he had a mine before building a mill, and when he was satisfied on that point, erected the necessary improvements. He has a pile of ore on the dump, estimated at 700 tons, which gives him plenty of material to work on. It is situated on or near the mother vein, and is undoubtedly a very valuable property. The ore is a mixture of slate and quartz, easily crushed. It contains free gold and sulphurets.

The at present worked drift in the Jefferson mine, at Garrote, is about half way in to the destination chute. In about 10 days the mill will be started on some ore already out.

Quartz Mountain.—*Independent*, Aug. 10: The Quartz Mountain gold mining company have struck a rich vein, about 18 inches wide, east of the mother lode, literally bespangled with gold. We understand that the vein at this place is about 12 feet wide and the pay streak about 18 inches. Further development will no doubt disclose something better than the owners of quartz mountain stock have ever seen.

A Curiosity.—*Independent*, Aug. 3: Bonnefoi & Co., of the Empire tunnel claim, mining in Table mountain, last week, struck in the forks of a hollow pine tree, measuring about two feet through, standing erect on the shore of the old river, some 100 feet under the pipe clay and lava formation. The company have sunk a vertical shaft, and are tunneling from the bottom to strike the old Caldwell channel, which proved so immensely rich in early days. They have already struck a shore, as indicated by round washed gravel and boulders, but too high for bed rock, as disclosed by the forks of the pine tree above mentioned.

Nevada.

WASHOE DISTRICT.

Con. Virginia.—Gold Hill *News*, Aug. 11: The daily yield of ore is from 200 to 250 tons. The ore is being sent to the mills for reduction as fast as extracted. Owing to the drying up of the water in the Carson river, the Morgan mill was obliged to stop, the Bacon and Trench mills at Silver City being substituted in its place. The repairs to the Consolidated shaft are being pushed energetically ahead, the heat still being intense and the progress slow. The long-continued spell of severely hot weather on the surface has, however, a very discouraging effect on all the operations of the lower levels. The north and south drifts on the 1850 level, between crosscuts Nos. 2 and 3, have completed a connection, which very materially assists the ventilation of that portion of the mine. The repairs to the main southwest drift connecting with the C. & C. shaft on the 1650 level are making good progress. The repairs to drifts on the 1300, 1500 and 1550 levels are all advancing rapidly.

California.—Daily yield, 250 to 275 tons of ore per day. There is no change of interest whatever in any portion of the ore-producing sections of the mine. Sinking the C. & C. shaft has made the usual fair rate of speed, and to day is down to the 2050 level. The flow of water is still strong. As soon as the shaft can be sunk deep enough to form a sump, opening the 2050 station will be commenced, after which a drift will be started to the westward to cut and prospect the ore vein. The repairs to the Consolidated shaft are making steady progress, but it will take several weeks yet to complete them.

Bullion.—Sinking the main incline is making excellent progress, the bottom still in quartz of a fine character. The upper part of the shaft is in quartz and low grade ore, while the bottom is in the clay of the footwall. The face of the east drift on the 1700 level is being steadily advanced, and is showing some fine stringers of quartz.

Sierra Nevada.—Sinking the south incline has made good progress during the past week, having passed entirely out of the ore into vein porphyry until yesterday morning, when a little ore and quartz were again struck in the lower southwest side of the shaft. It is now down 50 feet on the incline below the 2100 level. It is the intention to push the incline on down to the 2200 level before crosscutting the ore vein.

Ophir.—East crosscut No. 2 and the southwest drift on the 2000 level have been stopped temporarily, in order to furnish a supply of air sufficient to start up the 2000 winze. This crosscut had penetrated the quartz vein, and at the time of the suspension of the work was in soft vein porphyry, carrying streaks of quartz, and might or might not be through the ledge, the character of the formation being such that no correct judgment can be formed beyond the actual developments made. Sinking the joint winze below the 1900 level on the California line is making much better progress, the water in the bottom being almost entirely drained by the diamond drill hole on the 2000 level. Sinking the main incline was resumed again yesterday morning.

Justice.—The flow of water at the bottom

of the main incline has almost entirely ceased, it being necessary to run the pumps only about two hours per day to hoist the water coming from the drifts and seeping from the sides. The most important prospecting operations in the mine are being carried forward on the 1300 level, where the ledge shows a vastly improved and more favorable appearance.

LADY WASHINGTON CON.—The north drift on the 1300 level is steadily advancing, the face in quartz and low-grade ore of a favorable character. The prospects are that when crosscutting the ledge is fairly commenced, valuable ore developments will follow. The amicable settlement of the difficulties of the Alta, Benton, Boyle and Lady Washington companies, gives the Lady Washington a splendid opportunity to develop its valuable ground without any further dispute. By the terms of the compromise, the Lady Washington stockholders get 180 shares each of the new consolidated stock for each 100 shares held of the old stock, also the right of prospecting their mine through the Alta shaft by paying the cost of the same to the Alta company.

VERMONT CON.—Excellent work is being done by the contractors in sinking the shaft, about three and a half feet per day being the average progress. The timbering is being done in a very substantial and workmanlike manner throughout.

LEVIATHAN.—On the 750 level the lateral drifts both north and south are now in the black dyke formation immediately underlying the ore vein. Good stringers of quartz giving low assays are being continually cut through.

SUTRO TUNNEL.—During the past week the header has made very good advancement, running through easy-working porphyry and quartz, showing streaks and bunches of good ore. Within a very few days connection will be made with the main Savage incline, completing the best air circulation yet effected in the deep workings of this section. The header is to be continued beyond, when deemed advisable, but the probabilities are that the large water drain throughout the bottom of the tunnel will have to be made before running into any very heavy west wall water risks.

NORTH CON. VIRGINIA.—The shaft has been drained of water, the machinery all put in the best of working order, what repairs to timbers was necessary have been made, and work was regularly resumed with a full force of men at the bottom yesterday morning.

BELCHER.—The prospecting operations on the lower levels have been delayed somewhat during the past two days by the putting in of another large lift pump in the main north incline shaft. That will be finished in a very short time, when everything will be in the best condition for commencing the long deferred crosscutting of the ore vein on the 2360 level.

UNION CON.—Sinking a joint winze has been commenced at a point 515 feet east in the joint Mexican east crosscut on the south line on the 1600 level. This winze is intended to connect with the north drift on the 1700 level of the Ophir.

SAVAGE,—The repairs to the main incline and perpendicular shaft are each making good progress. The pumps have lowered the water until it is down to the long drifts of the 2100 level, which are being gradually drained as the water is lowered.

MEXICAN. — Cutting out for the winze chamber in the face of the joint Union Con. east drift on the 1600 level, at a point 515 feet east of its starting place, has just been commenced.

GOULD & CURRY.—Sinking the main incline has been resumed and is making slow progress. The flow of water at the bottom is intensely hot.

CALEDONIA.—The attempt to drain the water from the joint winze on the Caledonia line by means of the diamond drill has not so far been very successful, but promises to be more so in the next few days.

OVERMAN.—The 1600 station is completed. The east and west drifts on the 1600 level are rapidly approaching each other and as soon as joined together will greatly assist the ventilation of the level.

TROJAN.—The second station has been yielding a small amount of good ore, and the indications at this point are that a good paying body of ore will yet be found. At the fourth station the south drift has cut through a very heavy body of clay, and into a body of lively, white quartz, giving fair assays.

CROWN POINT.—The north drift on the 2300 level is making rapid progress toward the north line, having advanced during the week past at the rate of eight feet per day.

SILVER HILL.—The quartz and ore developments in the north crosscut from the north drift on the 800 level continue of a very favorable character.

HALE & NORCROSS.—The pumps are kept steadily running, and the water is now reduced to the long drifts on the 2100 level, so that the rapid progress with which the water has been extracted during the past few days is likely to be interfered with to some considerable extent, although if nothing happens to prevent, the 2100 level will soon be again ready for prospecting.

JULIA CON.—The water is drained down to the 2000 level, and the mud and debris is being cleaned out, preparatory to a resumption of work in the drifts and crosscuts on that level.

CHERRY CREEK DISTRICT.

THE MINES.—*Independent*, Aug. 3: Affairs at the Star mine are generally looking better. The lower drift on the 460 level, going west, has attained a distance of 138 feet, the face showing over four feet of fine milling ore. The winze on the 360 level is down 62 feet, and shows a fine vein of rich ore about four feet wide. The east drift on the 360 level shows streaks of mineral, and the prospect is good for a body of pay ore in that portion of the mine. The Star company's mill is temporarily shut down for a few small repairs, but will start to-morrow. The Lookout mine at Ruby hill has reverted to the owners, Messrs. Bird & Fitzhugh, through the failure of Mickle & Co. to pay the $5,000 for which it was originally bonded. One year ago Messrs. Bird & Fitzhugh were willing to take $5,000 for the mine, but now place a value upon it of $50,000, the result of developments in the meantime.

NEVADA ITEMS.—The copper mines, Railroad district, are said to be improving. The new Martin White mill is expected to bring back much of Ward's prosperity. A specimen estimated as worth $5,000 per ton has been taken from the Moosac mine. Tests of what was supposed to be pyrite cubes on ore taken from the Revenue mine have averaged upward of $11 per ton, 10% gold. The Cortez chloriders are shipping a portion of their ore to Salt Lake. The Excelsior mine on Prospect mountain has struck black metal assaying in the thousands. The Alexandria continues to hoist and ship ore which is netting them about $200 per ton. The Pride of the West, a mine south of the Jackson, is raising some fine ore. There are favorable prospects in the Industry and Piute mines.

NYE.

RICH STRIKE. — Belmont *Courier*: Within the last few weeks we have heard rumors of something big in the way of a mining strike, in a new locality within 25 or 30 miles from Belmont, but could obtain nothing definite in regard to locality or character of the ore, except reports of assays from outside places. About two weeks ago our County Clerk and Assayer went off mysteriously, but returned in a few days with a smiling but awfully sunburnt face; then came a display of ore from the new district which had been formed during his absence from town, and the announcement that it lay near the south end of the Toiyabe range—less than 25 miles from Belmont; that wood and water are abundant, that seven or eight locations had been made on ledges of free milling ore, assaying in some instances as high as $800 per ton, and several others on what is known as base ledges containing carbonate ore. The latter is considered by mining men and experts the best prospect for a surface development in the country; the lode is traceable for three-quarters of a mile, and opened across measures full 15 feet from wall to wall. The ore resembles the Gila ore from Reveille district, and persons who saw the Richmond and Eureka Con. when first discovered, say that the prospects of the California mines are much superior; of course there has been a rush out that way, and everyone who has returned tells the same story. Recent assays from the California, owned by Nicholl and Oder, range from $12 to $430 per ton; a sample from the croppings of the same ledge (Etna Co.) owned by W. H. Morgan & Co., assayed $58.71.

Arizona.

TAVAPAI.—Prescott *Enterprise*, Aug. 7: Mining industry is suffering on account of the drouth. Still our mines are not without hope. The Tiptop company's mill, at Gillett, is crushing ore with good success. Reports from the mines are highly encouraging. It is thought here by those who ought to know that the mill will keep on running regularly, and yielding a great deal of bullion. If so, the stock will soon take a step upwards and dividends will soon be in order. The Peck mill is allowed few spare moments. The shipments of bullion every week recorded in these columns give proof that the property is paying. Developments are still being made in the Tiger mine, which is said to be looking real well. There is a rumor in effect that the Signal company's mill will be removed to the Tiger. The Senator mill cannot be run, owing to the scarcity of water. The Aztlan mill is also idle. So is the Crook mill. John Holmes and other miners of Turkey Creek district, are working away. John says the district is all right. Several ledges are yielding good ore. News from Black Hills, Big Bug and other districts continues good. The placer miners of Lynx, Hassayampa, and the other auriferous creeks are not complaining. They very often arrive here with well-filled buckskin purses. Mr. Clarke and others recently struck very rich gravel in Bigelow's bar, below Lynx creek.

MOHAVE.—The Signal mill and mine are idle. The McCrackin mill is crushing about 100 tons of ore daily, which yields between $60,000 and $80,000 per month. A fine body of rich ore was recently discovered, so that everything down there is still all right. The Palmetto company are negotiating for a mill to crush their ore, which is said to be very rich. The Hackberry mill, in the northern part of the county, is doing well. The miners of Mineral Park and vicinity are still shipping ore to San Francisco. The newspapers of Yuma, Maricopa, Pinal and Pine counties, print good news in relation to mining and prospecting.

PECK AND TIGER DISTRICTS.—Mr. Cherry, who has just returned from a trip through the Bradshaw district, expresses a very favorable opinion of the mines there. He also visited the Peck, Black Warrior, Silver Prince and Crook, examining in all, between 40 and 50 mines. Says this is one of the best mineral sections in the country, and that one mistake made by mine owners and others here, is their cry about the scarcity of water. Our mountains are reservoirs, and it is only necessary to sink shafts of ordinary depth, and more water is obtained than can conveniently be gotten rid of. He would not hesitate to put up machinery on any mine which had been sunk on 100 feet, for fear of lack of water. Judge Silent, who accompanied Mr. Cherry, gave it as his impression that the Tiger district, including Bradshaw, ought to give employment to between 8,000 and 10,000 men, and the Peck district, within a radius of six miles, of from 5,000 to 8,000 men. The country is well situated for mines, both as to distinctness and permanency of ledges and facilities for working, fuel, lumber, water, etc. From Bradshaw basin the mineral outlet is evidently to the south. He thinks that unless the people of this section move in the matter, by opening up proper and increased facilities of communication, etc., that the business of these districts will be lost to Prescott, and that it is a matter of enough moment to merit some attention from business men. Says it is a part of the country for Arizonians to be proud of.

News in Brief.

THE Kansas wheat crop is especially fine.

FLOODS in India are causing great distress.

THE Hawaiians are complaining of too much rain.

THE Bear Paw placers are said to be worked out.

A NEW cuban loan will be issued in Madrid soon.

THERE has been a fresh outbreak of natives at Acheen.

GREAT mortality is reported on the west coast of Africa.

THE citizens of Yuma have had a touch of the Indian trouble.

THE treaty of Berlin has not brought entire peace to Europe.

JOHN H. P. HOYT, of Michigan, has been appointed Governor of Idaho.

THE Estremadura insurgents have been defeated by General Darmario.

CUBAN merchants and planters complain of the high Spanish duties on sugar.

THE grasshoppers cannot damage Minnesota crops seriously this season.

A NEW palace is to be built for the King of the Sandwich Islands at an expense of $50,000.

SPARKS from a thresher burned up about $7,000 worth of property on Arque's ranch, Hollister.

SMALL-POX is prevailing in Salt River valley, Arizona. Two deaths have already occurred from the disease.

GEN. GRANT has been received everywhere in Norway with extraordinary enthusiasm, crowds following him about.

SIX HUNDRED journeyman shoemakers of Chicago struck, August 6th, for an advance of $3 per week.

SEATTLE shipped more coal in July than during any previous month, the total being 14,001 tons.

THIRTY thousand dollars' worth of books were added to the Princeton College library during the last year.

IT is said that a new silver and electro-gilt counterfeit in the shape of a quarter eagle is in circulation.

A PROTECTIVE association of flour men, to prevent wholesalers from retailing, has been formed in Philadelphia.

ASSESSORS' returns from 90 Massachusetts towns show a loss in valuation of nearly $2,000,000 the past year.

A BILL allowing women to vote in school meetings has passed both houses of the New Hampshire Legislature.

GOVERNOR IRWIN has offered a reward for the arrest and conviction of the Grand Island murderer or murderers.

THE town of Alta, Utah, which was destroyed by fire on the 1st inst., is being rapidly rebuilt in a more substantial manner.

THE Hawaiian Legislature has made an appropriation of $38,000 as a subsidy to the Pacific Mail Steamship Company.

FLOODS have so damaged roads and railways, that communication is entirely suspended between Moldavia and Wallachia.

ON August 6th, the coal shed of the Copperopolis railroad, Stockton, was burned together with its contents, 100 tons of lone coal.

THE Porte has warned the Powers that the Mussulmans in the districts annexed to Montenegro and Servia, will rebel.

THE passenger train which left Pittsburg August 7th, collided with a freight train. Several killed and many wounded.

THE officers and directors of the Bank of New York have taken the initiatory steps to reduce its capital from $3,000,000 to $2,000,000.

IN the House of Commons, August 6th, Northcote, moving the supplementary estimates, said the House must provide for a deficit of £4,300,000.

AT Boston the car shed of the Eastern Railroad Company was burned on August 5th, with six passenger cars and two Pullman cars. Loss, $55,000; insured.

A PROCLAMATION has been issued in Herzegovina, announcing that all persons who offer resistance to the Austrians will be tried by drumhead court-martial.

IT is said that 47,000 Russians are sick in Bulgaria, and constant reinforcements are necessary to keep up an effective army. General Todleben is down with typhus.

The demand for the standard silver dollar is rapidly on the increase.

More attempt will be made to obtain artesian well water in Stanislaus county.

THE new American Theater, Philadelphia has been sold by the Sheriff for $70,000.

AN overissue of Pennsylvania State Sinking Fund bonds has been discovered.

FEVER is increasing at Nicoria, Cyprus, which place is unquestionably very unhealthy.

ANOTHER revolutionary plot has been discovered and guarded against in Venezuela.

AUGUST 12th, a Russian cutter exploded in the harbor of Nicolaieff, killing 34 persons.

THERE were 104 deaths from yellow fever, and 66 from small-pox in Havana in July.

A COLORED man in Texas, believing when the eclipse came on that the end of the world had arrived, hastened his own and his little son's journey over Jordan by the aid of a hatchet and a razor.

Continued from page 98.

of their money would be distributed in the vicinity of the forest. The instances of farming operations being successfully conducted by corporations or even by absentee landlords are very rare, but the conditions of arboriculture are somewhat different and the disadvantages of corporate management are by this plan reduced to a minimum. This plan is based on the gain to be derived from the aggregation of small savings, which has been so conspicuously illustrated by our Philadelphia building associations, which have, in fact, proved to be the most successful application of the principle of co-operation.

City mechanics have spare money, but about the only spare commodity that farmers have is time. If they could invest a fraction of each year in the stock of a forest corporation, it would grow into money in due course. The legislature should provide cheap processes for the legal organization of such associations, and the idea becoming sporadic, we should see it, all over the State, in suitable localities, take root and thrive.

In some places fence timber would pay the best dividend; in others railroad ties could be grown to a profit; whilst in others the more valuable kinds, such as ornamental woods, like black walnut, would be the only kinds that would pay. A "State forester," whose services could be had at, say, $2 per day and expenses, could give valuable advice in the selection of grounds as to aspect, soil, etc., the proper kinds and methods of planting and culture, and, ultimately, as to marketing. In Europe, the initiative to industrial movements is often given by the government by the establishment of schools, etc., but in this country the people are competent to the initiative in every enterprise of pith and moment, and these neighborhood forests would constitute in themselves objective schools, awakening and producing a liberal interest. The Forest Boards would come to be no mere wooden figure heads, but fully equal to every tough, knotty subject, and their discussions and processes would awaken a great deal of attention to this very important subject.

The farmer, from his isolation, has heretofore been denied participation in co-operative movements. He is fast learning the advantages to be gained from combined and concerted action. Such forest corporations, as are here suggested, would prove additional centers of usefulness and incentives to self-helpfulness. There would be no reason for citizens to fear to supplement the capital of the farmers, provided the latter contributed at least 50% of the capital at the start; indeed such investments would probably constitute the very safest and best that could be made. HORACE J. SMITH.

George's Hill, Philadelphia.

A Native Textile Plant in Merced County.

EDITORS PRESS:—I send you herewith a sample of the fiber, dead stalk and green leaf, of a textile plant which I find growing on the bottom lands of the Merced river, in the vicinity of Snelling. The plant is here known as *shoestring*—the name no doubt being suggested by the stringy and ragged appearance of the dead stalks after being exposed to the winter storms. This sample of fiber was stripped from the decaying canes of last year's growth, and is perhaps not seen under the most favorable conditions to afford a correct estimate of its value; nevertheless, I believe that its great strength, even in its present condition, and the large yield of the plant, are qualities which render it worthy of investigation.

The plant is perennial. It grows luxuriantly on all the good corn lands along the river, and by all corn cultivators is voted an intolerable nuisance, as it strong roots have to be grubbed out of the way of the plow. It is not uncommon to see from 50 to 100 ratoons from a single root; and they seem to go on increasing from year to year. I believe that it would only be necessary to plant it once, and then the chief employment would be to keep it from becoming too dense a growth. The canes, or ratoons, grow from six to nine feet high, and would evidently produce an immense quantity of fiber per acre.

I have said that it grows on all good corn lands. It is not, however, to be found there only, as I find it on the driest and most gravelly places on the river bottom lands, and I believe it will grow on any deep soil that will produce wheat or barley. Its mode of propagation is plainly suggested to everyone who has had to grub it out of the corn-field, as every piece of root that is left on the ground becomes a new plant, and in a few years, if not removed, an ever increasing thicket of canes.

If the fiber of this plant is found to be well adapted to the manufacture of the coarser qualities of sacks and cordage, a question of vital interest to the prosperity of the State would seem to be easily solved by its cultivation.

J. R. HORSLEY.

Snelling, Cal.

[The plant, as nearly as we could determine from the leaf, is probably *Psoralea macrostachya*. The fiber seems good and strong, but no better than that yielded by many other plants. There is little opportunity of turning it to account, because other material is so cheap. For paper making, for example, nothing is better than old manila rope, and this, the paper makers inform us, can be had for $20 a ton in as large quantities as they can use. The fiber which our correspondent sends could not be cleaned and prepared for nearly so cheap a price. There is no trouble in producing raw textile material; the difficulty lies in getting the expensive machinery which is needed to manufacture it and then produce enough of the finished article to make the investment of capital profitable, this is the problem to be solved.—EDS. PRESS.]

La Belle Cascade.

The engraving on this page gives the reader a glance at a pretty little piece of California scenery located in San Gabriel valley, Los Angeles county. The engraving is made from one of Mr. Watkins' admirable series of photographs of natural scenery in this State. The charming waterfall has a wide local fame, but is only one of many beautiful "bits of nature" which the locality possesses. For a description of the scene shown in the engraving we are indebted to an accomplished writer, resident in San Gabriel, who modestly styles herself "Ecila." She writes as follows:

LA BELLE CASCADE, SAN GABRIEL VALLEY.

A delightful trip, and one that the residents of the San Gabriel valley are fond of taking, is to the lovely little fall in Eaton's canyon known as "La Belle Cascade."

If you would like the jaunt you leave the Mission San Gabriel rather early in the morning—for you will need the whole day for your pleasuring—and drive or ride some six or seven miles on a good hard road to the mouth of the canyon in the San Gabriel range. Here you must leave your comfortable carriage and pet pony, and travel the remaining mile and a half on foot, for the canyon narrows very perceptibly at times, and you will come to places where the most experienced mountain horse could hardly gain a foothold.

Now you reach the stream which you will cross 20 or 30 times, creeping along the trunks of fallen trees, or jumping from rock to rock on to the slippery stones—very likely giving your feet a dip in the cool water, unless you have taken the precaution to wear rubbers.

How clear and sparkling is the water as it burries along, forming miniature cataracts and rapids!—forming also the still deep pools in which the wary trout finds a hiding place!

Near the stream grow the gorgeous scarlet larkspur and honeysuckle, and a dainty little flower of a delicate buff; and beyond, halfway up the steep hillsides, are yuccas in great profusion—the time of blossoming is past, however, and the immense peduncle bears only the green fruit—not a single waxen flower remains.

Meanwhile your pathway seems, at each step, to grow more rugged and stony. If you are unaccustomed to mountain climbing it appears impossible to keep your footing on that barren ledge. You look up and see huge rocks threatening to topple over and crush you out of existence. You are half inclined to turn back, and doubt if any waterfall could repay you for this long, wearisome tramp. Still you press on, not to be outdone by the rest of the party, and as you round a vast mass of rock and earth covered with a thicket of tangled vines, "La Belle Cascade" smiles upon you. In front of the fall are immense stones, worn smooth by the waters, where you can rest while you enjoy the charming picture.

The cascade is rightly named "The Beautiful" as it flows from a cleft in the rock, and descends some 30 or 40 feet in a sheet of white foam; and then the streamlet rushes along over the boulders, creating a succession of bewitching little waterfalls.

On either side and beyond the cascade tower rocky walls, all their ruggedness softened and beautified by a covering of fairy-like moss, maiden's hair ferns and delicate trailing vines.

On all sides the lofty hills seem to shut you in, and directly overhead you catch a glimpse of the blue California sky; but the most pleasing part of the whole scene is the foaming water as it pours down over the walls of living green.

Well has it repaid your toilsome trip through the briars, and your scramblings over the slippery rocks, and you would willingly journey twice as far, provided you could find another waterfall as charming as "La Belle Cascade."

A Wine Exhibit at the Mechanics' Fair.

J. H. Culver, Secretary, has issued the following circular to wine producers, concerning an exhibit of native wines at the Mechanics' Institute fair, which will open August 13th:

After mature consideration by the Board of Managers, it has been decided to invite wine growers and merchants to co-operate with them in rendering the exhibition of pure native California wine at the forthcoming fair as worthy of the occasion as possible; and also for the purpose of having them submitted to experts, *not for competition*, as between individual growers or merchants, but mainly with a view to obtain a report on their respective characters and general vinous properties.

The jury will be composed of gentlemen who have no personal or pecuniary interest, but only a scientific one, in wines. A gentleman from Australia, the Rev. Dr. Bleasdale, who is residing here for a time, who, it is well known, has done much to foster and advance the vineyard industry in Australia, and whose critical judgment upon pure wines has long been recognized and highly esteemed, both in Australia and England, has agreed to take part in the present exposition, and also to favor the Managers with a report upon the samples submitted. The Managers consider that such an independent report by a distinguished savant would benefit the wine industry both in this country and abroad, by giving reliable information on the extent, variety and goodness of the results obtained hitherto in this branch of California agriculture.

It will be sufficient to send three bottles of each kind to lay before the judges; but it would be well to send also some empty *labeled* bottles to place on shelves in the hall. The wine should be sent with the least possible delay, that it may have time to rest and recover condition. Young wines are specially requested.

I am to request vineyard proprietors residing at a distance, who may have agents in San Francisco, but who may not care to send samples, to authorize me to obtain from them the samples of wines which they consider most interesting and characteristic of their district, or of their methods of treating and maturing them. A blank form will be sent to each exhibitor, upon which he is to give some facts concerning his manner of growing the grapes, etc., and the kinds of grapes used to make the samples of wine shown. A full and complete report will be prepared, published and sent to each exhibitor. All packages to be marked "Wine Exhibit," 13th Industrial Exhibition, San Francisco, Cal., and the charges prepaid.

The blank accompanying this circular has spaces from which to answer the following questions:

1. Name of wine, and number of samples sent in?
2. Age of wine, or date of vintage?
3. Name of vineyard?
4. Approximate yield per acre?
5. Name of locality or district?
6. Names of kinds of grapes generally grown in the district?

Space is also provided, in which to give any information as to the character of the soil, and the details of the system of cultivation.

Better Than a Bonanza.

We have been shown some specimens of zinc blende taken from the Gold Hill mine, Boise county, Idaho, which, besides the usual base metals common to that mineral, carry a large percentage of gold and silver. The particles of gold in this ore show a tendency to arrange themselves in an acicular form, some of the larger of these needle-like shoots being over an inch in length and the tenth of an inch in diameter, from which size they dwindle to a mere down of microscopic dimensions. This mineral occurs in the lode from which these samples were taken in small bunches, very little having been met with until a depth of 100 feet was reached. Below that level it has been found to increase at a rate that promises to ultimately very much augment the gross production of the mine.

But the above, though a curious feature, is by no means the point of greatest interest connected with this Gold Hill property. It has a history from which some useful lessons may be gleaned. In the first place, this mine lies afar off from San Francisco, its principal base of supplies, and near the center of a Territory more distinguished for its failures than for its successes in vein mining. This enterprise has never enjoyed the advantage of newspaper notoriety, if that be an advantage. Very rarely has anything been said about it by the local press of that region, nor have the Commissioners of Statistics more than alluded to it in any of their volumes. And this is all proper enough, for the Gold Hill is by no means a great mine. It has revealed no bonanza, created no millionaires and sent off no startling shipments of bullion. There has been nothing sensational or showy about it. The proprietors have simply developed here a medium sized ledge of fair grade ore, on which they have run their 25-stamp mill continuously for eight years, keeping in their employment, meantime, at good wages from 40 to 60 white men, who have received their earnings in cash at the end of every month. The owners, commencing with but little capital, have paid for this mine and some eight or nine others supposed to be equally as good, have defrayed the expense of opening it up and outfitting it with steam mill and hoisting works and made some money besides; the whole having been accomplished with the net profits derived from working this one ledge, and that under about as many disadvantages as usually surround undertakings of this kind.

It may be asked, What is the lesson to be drawn from these facts? Simply this: They tend to show how little success in mining is dependent on extraneous conditions and almost wholly on the character of the men who engage in it. They tend to show that if a small company of the right kind of men take it upon them to go out on our mineral lands and there build up a paying mining enterprise, they will be pretty sure to accomplish that end, even though their pecuniary means be limited and they have many difficulties to contend with at the start. They tend, moreover, to illustrate how possible it is for a company of that kind to dispense with the machinery of the Stock Exchange, and even the aid of the capitalist, if only they take hold with a will and manage their affairs with honesty, energy and economy. There are in Idaho hundreds of ledges just as valuable as the one from which this Gold Hill company have obtained these tolerably good results. Arizona, Utah, Nevada, and, in fact, our whole metalliferous domain abounds in lodes which, as in this instance, require but the application of persistent, well-directed labor, supplemented by some small means to insure equally good returns.

With this company the strictest economy has from the beginning been a cardinal point. They have never let their expenditures get ahead of their receipts, nor have they improved beyond the requirements or obvious prospects of their mine. They have had no salaried officials nor fine offices in San Francisco; no shares for sale

on the Stock Board, and no useless and oppressive assessments. But while frugal they have not been niggard. They have never sought to cheapen wages nor to supplant white by Chinese labor. The profits of their mine have been widely distributed, having been largely shared with their own workmen and the surrounding community. Nothing has been unjustly taken here from the poor who could ill spare it to be given to the excessively rich who did not need it.

The ledge of this company, though a regular contact vein, is, as before mentioned, not a very large one, its average width being not over six or eight feet. The ore is a highly sulphureted, gold-bearing quartz, so decomposed that it can be mined and milled at a small cost. The vein has been quite thoroughly opened by means of shafts and tunnels to a depth of 300 feet, being 250 feet below the line of permanent water. The mine is outfitted with a 25-stamp steam mill and steam hoisting works, all first-class in every particular. The ore here yields about $10 per ton in free gold, besides a large percentage of sulphurets. Of the latter some 6,000 tons have been accumulated at the mine, which, after concentration, range in value from $25 to $150 per ton. Being inexperienced and without apparatus for the treatment of these sulphurets, the owners of this mine are desirous of contracting with competent parties for their sale or to have them worked on such terms as might be agreed upon, and which on the part of the company we are prepared to say would be exceedingly liberal. As the facilities for cheaply handling these sulphurets are here very great, water being abundant and wood obtainable at very low rates, this opportunity ought to attract the attention of the process men on this coast. Thomas Mootry, Jr., one of the principal owners of this mine, is now in San Francisco and ready to negotiate with parties prepared to reduce these sulphurets successfully.

Wire Tramway in Chile.

From plans, photographs and descriptions furnished us by Mr. John Samson, an engineer lately in the employ of the Chilean government, we are enabled to give the following account of a wire tramway put into successful operation some years since on the coast of Chili by that gentleman.

The object of the tramway is to carry the coal from the mines on the Pacific coast a few miles south of the port of Lebu to the harbor of that town for shipment. Lebu is south of Valparaiso; its harbor opens to the north. The shore from the town to the mines is very precipitous, and of such material as to preclude the possibility of running an economical railroad. Moreover, the ocean is frequently so rough that the coal could not be transported by water. The only practicable plan was to construct a tramway.

The system employed is, in the main, that invented by Chas. Hodgson, of Loudon, but some necessary improvements have been made by the engineer who carried the work through. The main principle of the tramway is, of course, known to all our readers. An endless wire rope is made to pass around large drums at each end of the road, and is supported at about every 60 yards on vertical grooved wheels upon the tops of substantial posts. On this rope the articles to be transported are suspended in buckets. The attachment of the buckets to the rope is described as follows: The attachment consists of a "rope-saddle," which is a block of wood about a foot long and three inches thick, and having a groove cut in it longitudinally. As its name indicates, it rests on the rope like a saddle * * * and has a pair of little wheels fitted on each side. The box is connected with the saddle by an iron hanger so shaped that the load always hangs in equilibrium beneath the rope. On arriving at a wheel, the rope-saddle slides easily over it, while the box passes clear beneath it. The adhesion of the saddle depends wholly on the frictional adhesion between the wood and the wire rope. The coefficient of friction determines the steepest practicable grade of the tramway. Mr. Samson found that one in six was about the limit. With rubber saddle-boxes it might be one in three. With a steeper grade, the boxes on approaching a wheel would slide back. At loading and discharging stations, the boxes require to be taken off the rope and brought to a standstill. For this purpose an iron rail is fitted up on each side of the rope at such points. On the arrival of a box the little wheels, with which the saddle is provided, run on to those rails, by this means raising the saddle clear of the rope, and the box may be then taken to any point desired.

The main tramway is two and one-half miles long. It makes two considerable curves, one of 20°, the other of 29°. These are passed by the buckets by means of iron rails, such as are used at the stations, but bent and inclined so as to carry the buckets by their own gravity and momentum around the curves. The route is so irregular that, in some cases, posts of great hight have to be used, some being 60, 70, and even 90 feet. One of the spans is remarkable for its length. It is over a deep gorge on the coast; the rope is stretched for 1,080 feet, with but one intermediate support, and that below the line of the posts on either side.

The line is driven by a double cylindered engine of 24 horse power nominal. The driving drum is 12 feet in diameter and wood-lined. The rope is of steel and about an inch in diameter. The boxes contain about 350 pounds of coal, and weigh, with hanger and rope saddle, 180 pounds. The rope is driven at the rate of four miles per hour. In 1873, the average daily carriage was 100 to 150 tons. The terminal are on the same level; the rope passes over a ridge 390 feet high. The ascending and descending buckets balance each other so nearly that the engine is relieved of much labor.

At the end of the main tramway on the coast the buckets are switched off, by means of the iron rails, on to a branch rope which carries them down the bank to the mine. At various stations along the main rope, coal is received from intermediate mines.

Notwithstanding the large amount of work accomplished by this tramway, it works without the slightest noise. The constant, busy, yet quiet circuit of the loaded and unloaded buckets, up and down the incline, is said to present a very pleasant picture. But it is from an engineering point of view that the work is most remarkable. In it we see great natural difficulties overcome; steep gradients, curves and wide spans have been passed, rough ground without levelling, ravines without bridges.

Useful Information.

A Substitute for Gutta-Percha.

The *Polytechnic Review* translates from the German of Dr. W. Reigler an account of "balata," a substitute for gutta-percha. Balata, which has only been known for a short time, is inferior in the extent of its uses to caoutchouc, but surpasses gutta-percha, and is said to have already become an important article of commerce. It is the milky sap of the bully-tree, that flourishes on the banks of the Orinoco and the Amazon, in South America. The operation of winning the gum is similar in every respect to that employed with caoutchouc and gutta-percha. It resembles gutta-percha so closely in its general properties, that much of it is shipped from Guiana and sold yearly for gutta-percha, although it has many points of superiority. It is tasteless, gives an agreeable odor on being warmed, may be cut like gutta-percha, is tough and leathery, is remarkably flexible, and far more elastic than gutta-percha. It becomes soft, and may be joined piece to piece, like gutta-percha, at about 120° Fahr., but requires 270° Fahr. before melting (higher than gutta-percha).

It is completely soluble in benzole and carbon disulphate in the cold. Turpentine dissolves it with the application of heat, while it is only partially soluble in anhydrous alcohol and ether.

It becomes strongly electrified by friction, and is a better insulator of heat and electricity than gutta-percha, on which account it may find considerable application for electrical and telegraphic uses.

Caustic alkalies and concentrated hydrochloric acid do not attack it; but concentrated sulphuric and nitric acids attack it as they do gutta-percha, which it closely resembles in all other properties.

We have in balata, says Dr. Riegler, a body characterized not so much by the possession of new properties, but rather a new member of the group of useful elastic gums, taking rank between caoutchouc and gutta-percha, which may, under many circumstances, be found to be more valuable than either; and it is a matter of congratulation that the world has been supplied with another and abundant source of elastic gum to swell the supply which the rapid destruction of these trees threatened to seriously diminish.

Imitation Shell and Pearl.—Imitations of lapis lazuli, tortoise shell and mother-of-pearl have been manufactured in Austria for more than 12 years. The "shell" imitation, which is in greatest demand, may be made on glass, and consists of a layer of clear gelatine, on which the characteristic markings of the tortoise shell are produced by dotting it with a concentrated solution of vesuvine (aniline color) to which a handsome reddish shade may be given with fuchsine; or the solution is spattered over the surface and the drops allowed to run together. When dry, the whole is covered over with a coating of glue. The imitation of mother-of-pearl is more difficult. It may likewise be made on glass, and contains in the first gelatine layer a concentrated solution of some salt. Several salts may be chosen for this purpose, such as white vitriol, epsom salts, etc. After the crystallization of this salt solution, and when dry, essence of pearls is spread over the whole. The latter material is made from the exceedingly fine and silvery-shining belly scales of the bleak, which are scraped off and washed out thoroughly. To the gelatine layer thus prepared, a coat of glue is applied and the article is then complete.

Tula Silver.—The composition of tula silver, which was long kept a secret, has been discovered, at last. It consists of nine parts of silver, one part of lead, and one part of bismuth. The metals, in the proportions stated, are melted together. The addition of sulphur gives the beautiful steel-blue tint, for which it is so highly prized.

Telephonic Carbon.—The carbon disk in the telephone is lampblack, collected from kerosene or other light hydro-carbon. It is compressed into a button under great pressure.

Millstones.

In the proceedings of the Fifth Annual Convention of the Millers' National Association, held in Indianapolis, in May last, there appears a valuable report on mill machinery, prepared by Mr. Joseph F. Gent, of Indiana. Among the practical suggestions given are several relating to millstones. In selecting a stone, Mr. Gent counsels preference for a medium stone in every particular, not too porous or open, and neither extremely hard nor soft. If a close stone is desired, one should be selected that has every block close alike; if an open stone is preferred, the same rule should govern, but in no case should a stone be chosen in which the openings or porous parts exceed one-tenth of the whole face.

As regards dress, one in which every furrow runs to the eye, is preferred for high grinding, and in no case is a dress advisable which makes less than every other furrow a leading furrow. For most kinds of wheat grown in the northwest, furrows should be eight-sixteenths inch deep at the eye, and one-sixteenth to three-thirty-seconds deep at the skirt. They should be wide enough to insure perfectly cool grinding, and to discharge the chop free and round. With stones grinding on winter wheat, the furrows required are equal to very nearly two-thirds of the entire surface of the stone. Draught can only be decided upon when the dress to be put in, the amount of grain to be ground per hour, and the speed and diameter of burrs, and quality of stone are considered. Mr. Gent states that, with a medium close stone, four feet in diameter, at a speed of 130 revolutions per minute, to grind five and a half to nine bushels per hour, every furrow leading to the eye, three and a half inches would give probably a satisfactory result.

If the old-fashioned stone, with small eye, is used, the eye blocks should be kept a little below the face of the stone; or, in other words, after applying the redstaff, it should touch the whole face of the stone, but show heaviest at the skirt, not in spots, but all the way around. If a stone, while grinding the proper amount of wheat, runs hot and glazes, the trouble is not enough furrow. The stone should, therefore, be taken up, and the furrow widened, until the proper amount is ground cool.

Anatomy of a Piano-forte.—A writer has taken the trouble to give the actual material used in constructing a piano-forte. In every instrument there are 15 kinds of wood, viz., pine, maple, spruce, cherry, walnut, whitewood, apple, basswood and birch, all of which are indigenous; and mahogany, ebony, holly, cedar, beech and rosewood, from Honduras, Ceylon, England, South America and Germany. In this combination, elasticity, strength, pliability, toughness, resonance, lightness, durability and beauty are individual qualities, and the general result is voice. There are also used of the metals, iron, steel, brass, white metal, gun metal and lead. There are in the same instrument of seven and one-half octaves, when completed, 214 strings, making a total length of 787 feet of steel wire, and 500 feet of white, covering wire. Such a piano will weigh from 900 to 1,000 pounds, and will last, with constant use, not abuse, 15 or 20 years.

Photographs on Silk.—Messrs. Allard & Gupot, silk manufacturers, of Lyons, are introducing a new industry—the production of photographic impressions on stuffs. They sent to a recent meeting of the Photographic Society several pieces of silk with a variety of photographic pictures printed on them—among others, some large medalions representing pictures of the old masters. These specimens are no less than 40 meters in length. The process by which they are produced is not given, but there is reason for believing that the prints are made with salts of silver. But however that may be, this application of photography, which, ever since the discovery of the art has been sought after and made the object of numerous, more or less successful, experiments, appears now to have been successfully realized.

Good Health.

What Banting Believed.

Now that newspapers, which indulge in the profit to be derived from quack advertising, are filling their columns with notices of nostrums for reducing corpulence, it may be well to call to light again the legitimate work which has been done to effect the desired leanness. Some time ago, William Banting, an Englishman, wrote a pamphlet on this subject, which is of a very practical nature, being chiefly confined to experiments on himself to reduce obesity. By dieting, he reduced his weight in a year from 202 pounds to 156, without any inconvenience whatever. He ate all kinds of meat, except pork and veal, all kinds of fish, except salmon, eels and herrings, and abstained from potatoes, parsnips, beetroots, turnips and carrots. Fruit was freely indulged in, and toasted bread. Green vegetables were not prohibited, neither soft-boiled eggs; cheese was sparingly used. He states confidently that quantity of diet may be safely left to the natural appetite, and that it is the quality only, which is essential to abate and cure corpulence. He tried rowing, gallons of physic and liquor potassæ, horseback riding, sea air and bathing, change of climate, but experienced no relief until he changed his diet.

In his pamphlet, he gives a tabular statement of the average of stature and weight of 2,648 healthy men, obtained from statistics prepared for the use of an insurance company. A condensed form of this may suggest to our readers about how much each one of them should weigh.

Stature.	Weight.
5 feet 1 should be	120 pounds
5 feet 5 should be	142 pounds
5 feet 8 should be	155 pounds
5 feet 10 should be	169 pounds
6 feet should be	178 pounds

Those who are desirous of increasing their weight will find abundant hints for doing so in what is above written. Some are by nature and constitution lean, and no amount of dieting could produce corpulence in them; but there are none who tend to obesity, that cannot, by a proper regimen, bring their weight within manageable limits. It is not advisable to make sudden changes in one's diet, or such changes as impair the general health. Experiments, carefully conducted, will soon satisfy the accurate observer what for him is the wise course. Mr. Banting advises that the experimenter in diet should have himself weighed every fortnight or month, regularly, that he may be encouraged by the steady loss in weight to persevere in his dieting, until he has obtained the goal of his desires.

Suicide and Insanity.

Probably the most exhaustive study ever made of the subject of suicide, in its medical, moral and legal aspects, is the article by Dr. John P. Gray, in the July number of the *American Journal of Insanity*. It is one of his lectures before the Bellevue Medical College, and may be taken as conclusive on several points of discussion connected with suicide. Dr. Gray has been professionally called in such cases more frequently, perhaps, than any other medical man in the country, and the conclusions he reaches are the sum total of his long experience and observation.

Dr. Gray contests the popular opinion that suicide is always an insane act. It is always an unnatural act; but in the large proportion of cases, if not in a majority, it is committed by sane persons. Dr. Gray does not undertake to deny that the mental state must be more or less abnormal, in the serious contemplation of suicide; but the differences between the mental condition of sane and insane suicides, is too obvious to be avoided. Delusion is "the test and touchstone in the diagnosis of insanity." When this state is present, the insanity of the suicide is beyond question. But the circumstances under which suicide is generally committed are not delusions, but facts. Overwhelming financial disaster, the commission of crime, the fear of impending disgrace, something of this nature generally drives to the desperate act; and that act proves not so much a state of mental derangement, as a deficiency in the moral education. Dr. Gray dwells with much earnestness upon the influence of education, and concludes that it is controlling, in all cases where the suicide is not insane. The moment the moral barrier is broken, the question of responsibility to a future for the act, the prudential reasons of family relations, of business with other men, character, etc., are quickly disposed of.

The discussion of this branch of the question leads Dr. Gray incidentally to a consideration of the influence of example in suicide. He sums up the result of his observation on this point by saying that "education and custom being powerful influences in overcoming the instincts of nature, and in inducing to suicide, the wide-spread publication of the names of suicides, the age, the sex, the mode, and the reasons, promote suicide by inducing imitation, and by lessening the horror of the act by familiarity with it."

The Health of San Francisco.—Valuable statistics relative to disease and mortality are given in Dr. Meares' report, showing the operations of the Health Office during the fiscal year. On a basis of 300,000 population, the death-rate was 18.35 per thousand. Last year the rate was 20.56 on the same basis of population, against 17.6 the previous year, on a basis of 272,345 population. The death-rate per thousand of the other populous cities the same year was as follows: London, 21.79; Liverpool, 26.56; Dublin, 27.94; Glasgow, 24.70; Edinburg, 21; Naples, 31.73; Munich, 33.90; Calcutta, 32.46; Vienna, 33.06; Havana, 40.86; New York, 24.32; Brooklyn, 21.52; Boston, 20.63; Providence, R. I., 18.81; New Haven, Conn., 19.70; Philadelphia, 18.80; Baltimore, 22.04; Washington, D. C., 25.42; Richmond, 21.27; New Orleans, 22.97; Cleveland, 17.91; and Chicago, 17.83. The rate was reduced over the preceding year at San Francisco, New York, Brooklyn, Boston, New Haven, Philadelphia, Washington, Richmond, Cleveland and Chicago. The rate was increased at Providence, Baltimore and New Orleans.

Cramps from Alkali Water.—A correspondent of the Fresno *Republican* says: Two men in the employ of Dunn & Donnelly, while driving sheep across the plains, were taken with cramps, and came very near going to their last resting place. Cause, drinking too freely of the creek water, which is warm and strongly impregnated with alkali and other substances equally injurious to the system, and which nearly always makes one sick. Sheep herders drink it, however, without any apparent ill effect.

SAN FRANCISCO:
Saturday Morning, Aug. 17, 1878.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Russel Patent Amalgamator and Gold Saver, 97. The Week; The Philosophy of Slickens; The Carbon Transmitter, 104. Opening of the Mechanics' Fair, 104-5. Edison's Phonomotor, 105. Patents and Inventions, 109.
ILLUSTRATIONS.—Russell's Patent Amalgamator and Gold Saver, 97. La Belle Cascade, San Gabriel Valley, 102. Edison's Latest Invention—The Phonomotor, 105.
CORRESPONDENCE. — The Wood-Gas Process, 98. Forestry.—The Value of Catalpa, 98-102. A Native Textile Plant in Merced County, 102.
MECHANICAL PROGRESS.—The Introduction of Steam Wagons; A Large California Thresher; A Simple Electric Lamp; Steam Crane; Ringing Engine-Bells by Steam; Compressed Air for Car Driving; Glass Hardened by Compression; Improved Fire Bars; Wheels and Axles; English Chimes, 99.
SCIENTFIC PROGRESS.—The Formation of the Tulare Plains; A Japanese Salamander; New Fossils; Size of the Tiger; Expansion and Atomic Weights; The Microphone and Insect Voices; The Smallest Insect; A Volcano in the Moon; Mr. Bennett's Chart, 99.
WHAT AND HOW?—On Suggestions for Inventions, 105.
MINING SUMMARY from the various counties of California, Nevada and Arizona, 100-1.
MINING STOCK MARKET.—Sales at the San Francisco and California Stock Boards, Notices of Assessments, Meetings and Dividends, 108.
NEWS IN BRIEF on page 101, and other pages.
USEFUL INFORMATION.— A Substitute for Gutta-Percha; Imitation Shell and Pearl; Tula Silver; Telephonic Carbon; Millstones; Anatomy of a Pianoforte; Photographs on Silk, 103.
GOOD HEALTH.—What Bauting Believed; Suicide and Insanity; The Health of San Francisco; Cramps from Alkali Water, 103.
MISCELLANEOUS.—La Belle Cascade; A Wine Exhibit at the Mechanics' Fair, 102. Better Than a Bonanza, 102-103. Wire Tramway in Chile, 103. The Mining Debris Trial, 97.

NEW ADVERTISEMENTS.

C. Leonard, Pattern and Model Maker, S. F.; Scientific Books, E. & F. N. Spon, N. Y.; Assessment Notice—Gover Mining and Milling Co., W. O. Wilson, Sec'y, S. F,

The Week.

The principal local event of the week has been the opening of the Mechanics' Institute Exhibition, which is now in progress. As yet everything is not in smooth working order, but will be in a few days. We ehall note what there is of general iuterest to our readers during the continuance of the fair,or that those unable to visit it may know something of the salient features. An item of interest in connection with mining mattere this week occurred at the meeting of the Julia mine on Wednesday. A resolution was passed to the effect that as the Julia company was pumping water and raising rock at heavy expense, and the Sutro tunnel was completed to a point near the deep working shaft of the company, the directors wore requosted and conetituted to make arrangement with the Sutro tunnel company for the epeedy construction of a lateral tunnel to connect with the Julia ehaft, for the purpose of draining the water and transporting the ore and mining material, and to improve the ventilation of the mine.

We notico that in making repaire in tho Consolidated shaft, where the heat is intense, a system has been adopted of taking the platforms ont of the shaft for eight hours during each day, which is fouud to greatly assist in cooling and ventilating the lower levels. We see that the effect of findiug a new ore body in Sierra Nevada has heen to infuse new energy into the prospecting operations, and the Directors have decided to work a large three-compartment working winze in the 600 crosscut eouth on the 1700 level. This winze is 600 feet east and the same distance south of the main shaft, which will locate it ahout 1,000 feet southeasterly of the perpendicular shaft. At that point it will be necessary to sink psrpendicularly a depth of 1,000 feet to reach the west wall. This shaft will probahly cut the north end of the new ore hody, and will he made the main working shaft, it heing the intention to erect powerful hoisting machinery over it.

The Philosophy of Slickens.

Everythiug in nature says to man, "Don't try to go too fast," and sverything points him to the uecessity of that which be has, in a mood of slack morality, allowed himself to call the "curse" of labor. He forgets his lessons as soon as he hears them. He is almost as ready to strive after perpetual motion to-day as he was to seek the philosopher's stone in the days of alchemists. When he hegins to learn about a pulley, he opens his eyes with wonder at the ease with which, as he helieves, he can create power and plans to lift the world. But enthusiasm cools when inevitahle experience forces it upon him that his apparent gain in power is a loss in velocity. He invents a machine that will make so many pius that he need hire now only half a dozen lahorers, where before he had a hundred. Immediately he discharges 94 pin makers, when he finds he has to hire about an equivalent nnmher of machinists to mannfacture and take care of the new inventious. He creates a corner in some market, say he huys up all the potatoes, and confidently hopes that, heing able to fix his own price, he is on the sure road to wealth. But he soon learns that while 10 persons may take a pouud of potatoes at oue cent, not half that numher will take it at two cents, and, may he, only one-tenth at three cents; and his career is checked. He is advised that by constant saving he can surely become rich. It is a great discovery. He does nothing hut save, and, at the end of a life time, a cramped, one-sided character holds up before him the narrowness of his aim. In everything an ahnormally large development in some one direction results in ahnormal want of development in some other direction, and every change of condition in any one department soon makes known a needed eorresponding change in every other department. When the miners found gold in gravel which they did not have to crush, hut needed only to wash, their advance was wonderfully rapid. With admirable energy they conducted water for hundreds of miles to serve their own purpose only. They hegan to wear down the mountains, and to fill their pockets with the gold. But stop, do uot go too fast! One condition of the problem was forgotten in their eolution. A voice of complaint comes up from the valleys miles away, and man's ingennity and energy must he taxed anew to overcome the latest difficulty.

The Carbon Transmitter.

On Monday, at the office of the American District Telegraph Co., 222 Sansome St., we had the opportunity to observe the surprising results gained by the use of Edison'e improved carbon transmitting and Phelp's receiving telephones. We heard clearly, at a distance of 15 feet from the instrument, although there was considerable noise in the room at the time. Whispering was also clearly heard hy puttiug the instrument near the ear. By the new apparatus, we are assured by Mr. Sahine, the manager, singing can he heard so clearly that a room full of people can enjoy it..

Those who remember the illustrated article on the telephone which appeared some weeks ago in the Press, will he interested to note the change which Mr. Edison has made, to secure the gratifying results which are uow realized. The following is a description of the new and the old forms :

In the latest form of transmitter which Mr. Edison has introduced, the vihrating diaphragm is done away with altogether, it having been found that much hetter results are ohtained when a rigid plate of metal is substituted in its place. With the old vihrating diapbragm, the articulation produced in the receiver is more or lese muffled, owing to elight changes which the vihrating disk occasione in the pressure, and which probably results from tardy dampening of the vihrations after having been once started. In the uew arrangement, the articulation is so clear and exceedingly well rendered, that a whisper even may readily he transmitted and understood. The inflexible plate, of course, merely serves, in consequence of its comparatively large area, to concentrate a considerahle portion of the sonorous waves upon the small carbon disk or hutton ; a much greater degree of pressure for any given effort on the part of the speaker is thus brought to bear on the disk than could he ohtained if only its small surface were nsed.

Chrome Iron Ore.—In our next issne will appear an article on the chrome iron ore on our coast. It will he prepared with a view to furnishing useful practical information to those who have the ore to eell, and who feel dissatisfied witb the present market.

It is expected that the Dayton, Sheridan & Grand Ronde railroad, Oregon, will he completed to Sheridan by September 1st, and to The Dalles by Octoher 1st.

Over 100 students have applied for admission to the University this summer; 90 succeeded in entering.

Superintendent Gillette reports ventilation in the Savage mine connection with the Sutro tunnel to he of great value.

Opening of the Mechanics' Fair.

We give helow the addrasses of Irving M. Scott, President of ths Mechanics' Institute, at the openiug exercises of the Thirteenth Industrial Exhibition, August 13th. Also the oration of J. W. Winaus, Esq., on the same occasion.

ADDRESS OF IRVING M. SCOTT:

Ladies and Gentlemen:—On opening the Thirteenth Industrial Exhibition, we resume the story of mechanical advancemeut, and meet to review the progress of the past yaar.

The story ie replete with the incidents of successful encroachment upon the domain of the unknowu. A numerous and persistent army of explorers have invaded the ehadow realms, and forced the heavens to yield part of their secrets; and hurrowing amid the inner recesses of the earth, have laid hare facts and couditious, which enables the scientist to resolve from the domain of thought, laws and principles heretofore unknown.

No year passes without extending the knowledge of mechanical principles, and ohtaining new victories over the forces of uature, making possihle the improhable. And the shadows of the past hecome the tangable realities of the present. Inventions and improvements take a step forward, during periods of financial and commercial prostration, universal depression releases from the iron grip of business drudgery hrains aud fingers, whose cunning takes from the field of speculation, and harnesses to the practical the suhtle elements of the uuiverse.

The past 12 months has been the openiug of a new hook, and a startled world is looking down a new vista, through the gates ajar, unlocked hy the discoveries of Edison. The enlarged knowledge of the science of souud bas swept the telegraph with its cumbrous, doubly-written, faulty messages aside, aud substituted the telephone. Will the phonograph of the future he a substitute for failing eyesight? Will the megaphone quicken tbe dulled organs of hearing? Shall the choicest gems of literature he transmitted through the medinm of mechanism.

In the future of mechanical science the inflections of the voice will be transmitted. The blind shall see, and the deaf hear!

Looking hack at what mechanic art has been, knowiug what she is uow, and seeiug all the professions, her willing handmaids, bringing their laurels to her feet; and from this standpoint looking forward aud upward to the future, the constructing engineer is the Colossne in the coming time.

The machinery of transportation and its twin sister, the telegraph, have destroyed the old conditions of supply aud demand. And from the old order of keeping a supply on haud, we pass to the new order of manufacturing on demand. This trausition has for a time disturbed the financial, commercial, political and social conditions; and it has hoen a year of adjustment. The relations of the mechanical classes to the governing classes are undergoing a change, which, when consummated, will prove the wisdom of a systeu, in which the humblest citizeu shares with the highest the duties of government.

The nation's interests will he safe with the mechanics, who have been taught to take the crude materials aud shape them iuto a harmonious whole. Taught to construct, taught to build up, taught to accomplish; trained to direct their energies in one direction for a common purpose. For they will take this discipline with them into the council chambers, aud prove that the strength of the Republic rests with the producers.

The civilization of this coast has done but little towards providing suitable amusements for the people; the theater on one haud, the saloon on the other, or worse, is all that this eommunity offers to the youug. These iudustrial exhibits supply the one great want of our social system; where amply arranged and sheltered from the cold, Industry brings her trophies, Science her laws, Art her progress, and, hlending in one harmonious whole, iuvites your attention, and promises to interest, to instruct and to amuse yon.

With these hopes and au abiding faith in the future, the Trustees decided to hold the Thirteenth Industrial Exhibition. The space applied for and occupied, the sale of tickets, the generous coutributions in every department, promise a euccessful issue. The Board of Managers are pledged to the most rigid economy. All partisan feelings and differences have been settled in favor of the hest interests of the Institute. Peace, order, harmony, law aud energy have joined hands and are pushing forward the goed work. And, with the support of the public, there is no euch word as fail.

ADDRESS OF J. W. WINANS:

Gentlemen of the Mechanics' Institute: It is a source of mingled pride and gratulatiou to this fair city, which sits enthroned upon the margin of the Occident, that an institution so beneficent as yours has grown up in ber midst into such a magnitude of usefulness and power. What more exalted object can we desire to contemplate thau a Mechanics' Institute, wbich seeks, by the force of combination and co-operative uuion, with patient, persevering and uuselfish effort, to promote the welfare of the great industrial mass, to cherish art, to foster manufactures—to crown labor king? For a brief interval the community has abaudoned the mart and the exchange—the brain has ceased to pulsate and the hand to toil in the pursuit of gain—that here, within these halls, ths people may meditats upou your civic triumphs, and exult in the achievements which your zeal and enterprise bave wrought. The field in which you labor, although exhaustless, is not new or unexplored.

Discovery and Development of Art.

Beforetime, in the earliest annals of our race, while yet the world was young, the euergies of man were concentrated on the discovery and the development of art. Not art alone in the loftier and more snhlimated types of its ideal beauty, hut universal art, including those more practical and useful forms, wherein it manifested all the skill and cunning of the craftsman'e hand. If Praxiteles could summon from the marhle, and Zeuxis from the canvas, the grandest creations of the sculptor's and the painter's art, the genius of Daedalus was no less potently impressed on the rare mechanisms he contrived. The Seven Wonders of the World, those miracles of human power, still hold an undisputed sway over the works of each succeeding age. Nor do these grand examples staud alone. The might, the ingenuity, the skill of man, were uo less prominent in the perfection which the useful arts attained. Many of these, although of world-wide notoriety and use, have been entirely lost. In vain do we strive to reproduce or rival the Tyrian purple or the Corinthian brass. The inscrutable texture of the ancient coins of bronze defies our craftiest attempts at imitation. No modern applications of skilled labor can construct an Appian Way; no nice artificer can fashion an Etruscan vase. Anon, when the shadows of the mediæval era had dispersed, and that long, starless night had ended in the dawn of art revival, the wood engraving of Durer and the superb devices of Celini, attained to such perfection as no later skill could rival. Yet the glory of the present age lies not in the pre-eminence which human genius can achieve or has achieved in isolated cases, hut in the generalization and diffusion which a common desire for the cultivation, not less than the extension of the mechanics' arts, and the promiscuous pursuit of those high objects, have established among the masses of mankind. It was a world of theory, that ancient world, but this modern is a world of practice.

The Necessity of Daily Toil.

In that earlier day the alternative of human labor was not the price of human life; hut now necessity prompts man to toil, and "necessity is the mother of invention." Yet though this originates in man's primal need for food and and raiment, it end not there. With the attainment of what is absolute for the support of life comes that "*auri sacra fames*," the inexorable greed of gain. Impelled by this, as a fresh and still more powerful incentive, the mind is constantly alive to plan, the hand to execute, those almost infinite contrivances which science aud invention bring to light, and labor consummates, for the aggrandizement of the coutriver, the comfort and enjoyment of the race. Hence railroads span the continents and telegraph structures stretch through air and ocean until the very ends of earth are brought together, and the varied nations of the globe are growing homogeneous by fusion. Hence the machinery of iron and the artillery of steam are superseding with their swift results the slow and labored processes of manuel employment. Hence new conceptions, new discoveries, clutching within their comprehensive grasp the little and the large, are modifying all our lives and changing the very conditions of our being. Alas! that learning and philosophy, and the devotion of the mind to litcrary themes, should be so grimly thrust aside hy the spirit of utilitarianism as it rushes onward in its stern career. And ever, as the age swings on, the abstract hardens into the concrete. Over crumbling theories and broken speculatious, over the ruins of metaphysical inquiry, over the reveries of the dreamer and the wrecks of the imagination, drives the car of progress. Yet we rejoice in our era, and expatiate admiringly upon the world's advancement.

"We are gods by our own reckoning and may well shut up the temples.
And wield on, amid the incense steam, the thunder of our cars,
For we throw out acclamations of self-thinking, self-admiring,
With, at every mile run faster—O, the wondrous, wondrous age!
Little thinking if we work our soul as nobly as our iron,
Or if angels will commend us at the goal of pilgrimage,
Why, what is this patient entrance into Nature's deep resources
But the child's most gradual learning to walk upright without bane?
When we drive out, from the cloud of steam, majestical white horses,
Are we greater than the first men who led black ones by the mane?"

Strange Mental Mutations.

Enceladus, nerved by a renovated etrength, renewe his struggles, thrilling the uations with his smoke and flame. Can you forbear to note what strange mutations the prevailing tendencies are working in the operations of the mind? There is less heed of the infinite in the more engrossing contemplatiou of the finite. Thought is busied with research into those means whereby the material elements can be converted iuto increased facilities for aiding humanity iu its pursuit of luxury and ease. The highest good for the greatest number is no longer a mere political maxim; it seeks to subject the whole realm of uature to the wants of man. Side by side with the heroes of the world no less exalted in its annals, side by side with the great and giant intellects, and

the famous men of every age, stands the noble army of inventors, as hallowed in the popular regard as the noble army of martyrs.

It is not my purpose, nor is the time congenial, to discuss the subject of mechanics, or the mechanical arts, in learned and didactic disquisition. I have only to commend a topic which, through your expositional display, reveals its character and teaches its lessons by examples. Here, at this periodic and imposing demonstration, this carnival of labor, examples multiply on every side. The click of the needle, the rumble of the wheel, and the sonorous din of the machinery, all speak their usefulness "with most miraculous organs," and tell us what results they are achieving for the welfare of the people in terms more forcible than scientific dissertation, in commendations more sincere than verbal eulogy, in tones more eloquent than rhetorical harangues. This life abounds in instances where the voices of Nature, and of Art, discourse a language more significant than speech. I can only point to your strenuous efforts in the past and urge you forward in your noble work by hortatory words which, though they glow but feebly on the lips, are prompted by the heart.

Relationship between Utility and Beauty.

As we wander through the spacious halls and labyrinthine avenues of that huge Pantheon of art which you have reared—as we listen to the clangor of its instruments of brass and the music that reverberates from its grand choir of iron voices; as we gaze up on the gorgeous panorama which these gathered works of art display in their variety, magnificence and beauty; as we stray through the gardens, teeming with fruit and flowers, luxurious with the foliage and growth of every clime; as we behold the costliest and rarest products of the loom, the multiplied creations of machinery, the strange and subtle emanations of inventive skill; as we survey the chambers quaintly ornamented with the garniture and decorations of the Gothic Age, the age of the Renaissance, the ages of the Louis, and the showy reproductions of Versailles; as we contemplate the gallery whose walls are studded with the delineations of pencil and brush, as we linger near the plash of fountains, or move amid the gay and brilliant throng that congregate around us in the festive spirit of the time, we realize in that seeming Palace of Aladdin, lit with its thousand lamps and glittering with mechanical splendors, how close is the relationship between utility and beauty; how intimately the capacity and love of man for labor, and its infinite creations, have identified themselves with his esthetic nature.

California is a marvel to the nations, alike from her material formation and the suddenness with which she sprung into the ranks of empires. Between her cloud-capped mountain ramparts on the east, and that vast ocean, whose surges lash her western strand, she lies, in her sweet isolation, a world within herself, secluded from the world without. Far and wide, throughout her spacious confines, the mineral and vegetable kingdoms have developed their most opulent resources. No other single State or realm upon the globe displays the wealth of nature in such countless forms or such abundance and perfection. To gather from each portion of her wide domain, from her vine-clad hills and fruitful valleys, her copious productions, diversified by the variance of her latitudes and climates; to collect from everywhere within her borders the rarest fabrications of the artisan and craftsman, and present them in a sparkling mass upon these annual occasions, inspiring thus the zeal of emulation by the contagion of example, and bringing the whole people into a consciousness of the extent of these resources, is but the beginning of your work. Yours is a broader empire and a loftier ambition. By systematic combination and properly directed effort, it is your purpose to increase the demand for labor while multiplying its results; to elevate the condition, extend the usefulness, promote the prosperity of the producing classes. Organization is power. In stimulating industry, not merely through the premiums which you bestow upon successful competition, but through the richer rewards that spring from the notoriety and patronage which industry acquires by your exertions, you augment production. Increase of production generates extension of demand.

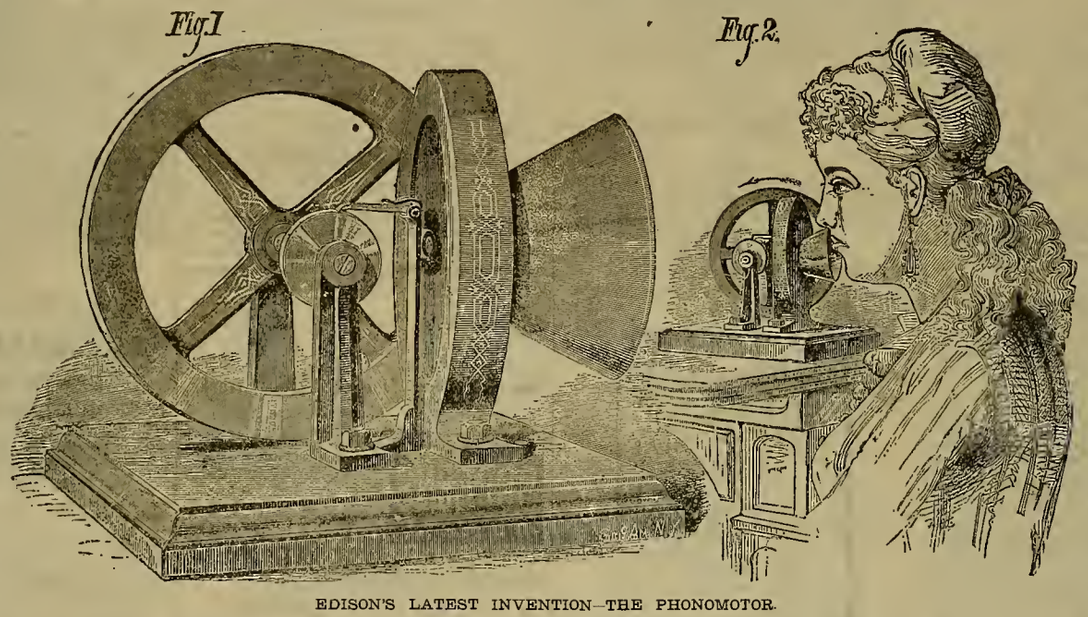
Sustaining the Rights of Labor.

In sustaining the rights of labor you give new courage to its faltering steps, new hopes to its desponding spirit. You lift it up to a closer equality with capital. You banish alike the arrogance of the consumer and the humility of the producer, so that the invidious and class distinctions of society are swept away, and the whole community, except where ignorance or vice creates depressions, is brought to stand upon a common platform. Well may the millions toil when roused to such a manly pride, when lifted to such lofty aspirations, when opened to such channels of success as your organization is creating. Even among the lowest ranks of men, these valued influences, while they ameliorate the condition, cultivate the moral sense and excite a thirst for knowledge. No stress of adverse fortune can force that man who clings unto his self-respect from realizing for himself and for his children the benefits of education. In the furtherance of this great principle you have collected on your shelves a library which you are constantly augmenting, and which, for rarity, extent and value, has no superior perhaps, save one, on the Pacific coast.

We come to-day to offer our homage at your consecrated altar. Your institution, prevailing over all the discouragements and obstacles which attended its creation—those influences which have crushed so many noble enterprises—has passed from the trials into the triumphs of time, and eventuated in a permanence of prosperity and power. Like Hercules struggling with the serpent in his cradle, you bore yourselves manfully, even in the very outset of your being; like him you have accomplished your 12 labors—those great industrial exhibitions which you have annually consummated during 12 revolving years. In this Institute, which has loomed up into such distinguished prominence and grand proportion, you have reared for yourselves a memorial more enduring than a monument of brass. Though the sword of the conqueror may fascinate and dazzle, yet it shines ever with a lurid and baleful gleam. Your honors are gathered from the plaudits of the people as the reward of earnest and successful effort, and, like the sunshine, they enliven while they glow. Flinch not, nor falter in your high resolve, but remain forever faithful to your trust, and let that venerated maxim, which the centuries have made immortal, *"Improbus labor omnia vincit,"* be graven in flaming characters upon your shield.

Edison's Phonomotor.

"Weak things have been chosen to confound the things that are mighty." Every once in a while the truth of this old Bible saying flashes suddenly upon us with new light. In every department of life we see once and again corroborated, and in no department, and among no class of men more frequently than in great inventions, and among great inventors. A student, struck with the idea that he is a genius, is given a difficult problem in mathematics. He sits down with his pencil, and, as if imagining that the complexity of the solution must be proportioned to the reported difficulty of the problem, he seeks his instruments and methods from the recondite branches. Arithmetic and geometry must be too simple for the unraveling of a knot that has such a reputation. So he applies analytics, and calculus and trigonometry. He gets a solution, indeed, but is a solution that covers folios with figures, and requires a day for each application. Meanwhile, some less aspiring youth, who dares not so much as lift up his eyes towards the sublime altitudes of calculus and her companion, smites upon his breast that he can use but the simpler forms of arithmetic, geometry and algebra. But he, too, brings out a solution. It is just as effective as the other, and is accomplished by the drawing of half a dozen well-advised lines. The mighty things are confounded. So, in contemplating the great inventions of the world, how many may have said: "If I had only had the slightest idea that it was so simple, I would have thought of that long ago." This is true of the steam-engine and of the telegraph. And it has, no doubt, occurred to thousands that the same is equally true of such of Edison's inventions as are likely to prove of most universal utility. It is, indeed, rather hard for one whose electrical bump has not been developed, to comprehend how Edison, or anybody else, can make two messages at a time go each way on a telegraph wire. The microphone and tasimeter require some little study to understand what principles lie at the bottom of them. But the phonograph is, to any one that understands the telephone, simple as the almost accidental way in which it was discovered. And so it is with the instrument which we are about to describe. In fact, the invention is so simple that a glance at the engraving taken from the *Scientific American*, is sufficient to explain the whole thing.



EDISON'S LATEST INVENTION—THE PHONOMOTOR.

The Phonomotor.

The phonomotor is a machine in which the vibrations produced by the human voice are applied so as to produce visible motion. The vibrations are allowed to first produce corresponding vibrations in a regular phonograph diaphragm (as shown in the figure). By means of a piece of rubber tubing placed against the diaphragm, the vibrations are then transmitted to a spring, which in turn vibrates in unison with the diaphragm, and thus with the voice. To the spring is attached a pawl. If any of the uninitiated do not know what a pawl is, they may be referred to the capstans of steamers. Those little hinged irons that, when the capstan has been turned a few inches, fall down with a click, and prevent the capstan from turning back again, will give one a very good idea of what a pawl is. The pawl on the phonomotor spring rests on the edge of a notched wheel. When the vibration of the voice vibrates the diaphragm, which in turn pushes the spring out, the pawl catches in a notch of the wheel, and pushes the wheel around a distance corresponding to the distance the spring vibrates. When, in its vibration, the diaphragm goes back, the spring goes back also, and with it the pawl. The pawl, in returning, catches on one of the other notches, and when the diaphragm comes forward again, the spring is ready to push the wheel around still further. So the phonomotor, with the power exerted by the voice alone, the wheel may be set into quite rapid motion, and after a careful series of experiments with this new invention it will become possible to measure and compare voices with regard to their strength and pitch. Many interesting discoveries concerning our vocal machinery will no doubt be made by careful observation of this instrument. And even before any careful and exhaustive experiments have been made, it may become possible to apply the machine so that, in some kinds of work, the voice may supply the place of hands, in which case, those poor armless and one-legged soldiers from the Tyrol and other ports of Ireland and the United States, who sing about our streets, may be set at some profitable employment, and the hand-organs on our street corners may be used to grind corn.

The engravings on this page which are taken from the *Scientific American*, show how simple the contrivance is. Fig. 1 shows the phonomotor displayed so that all its mechanism appears. Fig. 2 shows the way in which the sound is applied to produce the motion.

WHAT AND HOW?

In this column are printed all sensible inquiries relating to subjects connected with mining or relating to any matters of general scientific interest; also the answers to them as dictated by individual experience, or as furnished by correspondents.

On Suggestions for Inventions.

EDITORS PRESS:—In your last issue I see a letter from a farmer suggesting the invention of a "bean harvester." Now, this is a class of letters which I would like to see more frequently in the columns of the scientific papers. We all know that there are many intelligent men engaged in the practical operations of the arts, who, overcoming the tendency which habit brings to fall into routine, think of their work and reason on its processes. Such are the men who are most likely to see the imperfections of the present means employed and also the difficulties which stand in the way of improvement. But it may be that though at times a thought crosses their mind as to whether such and such a thing might not be done better still they have neither the time nor the faculty to act on their idea. But if they would publish their suggestions, vague though they might be, they would confer a benefit not only upon the particular art which they practice, but upon the world of inventors.

Every author must have felt at times, when he had to supply a certain amount of "copy," at a loss for a subject upon which to write, and he has been grateful for a lucky hint. So it is with the inventors. There are men amongst us who are "brimming over" with the inventive faculty, who pine for action, and who only seek a field to display their genius.

Let, then, the SCIENTIFIC PRESS assist in directing this force. It has already done much service in letting inventors know what has been done, and observant men are less likely than formerly to be treading in each other's footsteps. But still the young inventor is almost discouraged when he sees the long list of patents every month, and is led to wonder if there is anything left to invent.

The forthcoming Mechanics' Fair will most likely be visited by practical men from every part of the State. In looking at the machines exhibited, they will no doubt express their opinions; and these opinions, picked up by the quick ears of a reporter, and recorded in the columns of the *Mechanics' Fair Daily*, will give more than a passing interest to that periodical.

JOHN SAMSON.

Inquiry for Government Land.

EDITORS PRESS:—There is probably much land still open to pre-emption and homestead among the foothills suitable for fruit-raising. If some of your subscribers in San Luis Obispo, Ventura, or other coast counties, living in the vicinity of government lands, would give the information through the PRESS, they would confer a favor on many strangers in the State.—J. M. M., Orange, Cal

We have always encouraged statements of this kind. Any one knowing of good land subject to pre-emption, and desirous of building up neighborhoods by the incoming of settlers, will find us ready to print his account of the opportunities which may be found in his region.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Northern Belle, Aug. 5th, $5,176.43; Aug. 9th, $3,436.64; Aug 10th, $3,616.05; total for July, $109,678.56; Bodie, Aug. 8th, $31,500; California, Aug. 7th, $34,585.53; total for July, $348,191.68; Independence, Aug. 12th, $7,976.03; Tybo Con., Aug. 5th, $4,630.95; total to date, $9,978.72; Aug. 7th, $4,559-29; Aug. 9th, $4,546.14; Christy, Aug. 9th, $4,748; Leopard, Aug. 10th, $4,100; Con. Virginia, Aug. 9th, $91,626.78; total for July, $216,348.17; Standard, Aug. 9th, $37,661.60; total for July, $104,049.76; McCracken, Aug. 12th, $9,100.70; Manhattan, Aug. 13th, $11,400; Raymond & Ely, Aug. 5th, $7,326.16; Star, Aug. 9th, $2,642.33; Ontario, Aug. 5th, $5,672.74; Aug. 6th, $3,016.55; Aug. 7th, $2,604.12; Aug. 8th, $2,972.65; Silver Reef, Aug. 5th, $6,275.68; Aug. 6th, $2,750.66; Aug. 7th, $1,437.73; Aug. 8th, $11,552.15; Germania, Aug. 6th, $3,400; Old Telegraph, Aug. 7th, $1,000; Alexander, Aug. 15th, $4,501.74.

THE LEGAL TON OR BUSHEL OF BITUMINOUS COAL.—The recent Legislature of Pennsylvania passed the following bill in reference to what constitutes a bushel or a ton of bituminous coal. Heretofore a bushel of coal was 70 pounds. Now a bushel is 76 pounds, and a ton 2,000 pounds.

THERE are over $2,500,000,000 in railroad bonds and stocks which pay the owners nothing. There is $500,000,000 in iron furnaces and manufacturing establishments, and $600,000,000 in shipping, hopelessly tied up.

RHINISH CANAL.—A canal is to be made from Amsterdam to the Upper Waal (the southern branch of the Rhine), an undertaking which will doubtless prove of considerable importance to the towns on the Rhine.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free. Address

DEWEY & CO.,
202 Sansome St., N. E. Cor. Pine,
San Francisco.

Canadian Patents for U. S. Inventors and Patentees.

One Patent now Embraces all the English Provinces in North America, including the Canadas and British Columbia.

It is only recently that the Canadian Government has granted patents to United States citizens. In consequence hereof the many immensely valuable inventions patented in this country are now patented in Canada. Patents are much sought for and are readily disposed of at fair cash prices. In our country about three-fourths of all manufacturing is based upon patents, especially in the New England States no manufacturing business of any consequence is started without being protected by such. Our neighbors across the border have not been slow in observing and learning that inventions and patents are the foundation of all prosperity in manufacturing purposes. Hence all our patents for labor saving and agricultural machinery and innumerable improvements in home comforts meet a ready market in Canada. Inventors and Patentees should therefore not delay to secure their patents in Canada; many good inventions are already pirated by by Canadians, who, against law and right, appropriate United States inventions and have them patented in their own name. After a patent is granted it is extremely difficult to prove who is the first and original inventor. Therefore, inventors and patentees to be safe, you will have to secure your patents in Canada without delay. We have facilities for securing Canadian patents second to none, Our charges for securing Canadian patents are about $65. A model is required.

Inventors and patentees! do not delay and lose your opportunity. Things may change. With model and description of your invention remit $25, and we will prepare all drawings and documents and forward them to you for signature. In about 30 to 50 days we can return your Canadian patent.

DEWEY & CO.,
Patent Solicitors, S. F.

TESTING AND WORKING SILVER ORES.—This is the title of an illustrated work of 114 pages, for Miners and Prospectors, by Chas. H. Aaron, published by Dewey & Co. It is written for miners, in plain language, and with all necessary details in description. The author describes the different processes of roasting ores, the appliances, methods of testing ores, testing for a process, working samples, treatment of base metals, use of chemicals, leaching processes, different kinds of crushing apparatus, etc. This little work abounds with useful hints to miners and prospectors, and is written in a practical style. Price, post free, $2.00. Address, Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome St., San Francisco.

THE EXPLORERS,' MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 83 engravings. By J. S. Phillips, M. E. Price—cloth, $10.50; in leather, $12; postage 50 cents. Sold at this office.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver ores generally, with 150 Lithographic Diagrams, 1867. The most complete treatise. Published at this office. Price, $7.50. Postage, 50 cents extra

TO LUMBERMEN.

The Property of the Duncan's Mills Land and Lumber Company,

Sixty miles from San Francisco, at the terminus of the North Pacific Coast Railroad, Sonoma County, is offered for sale on very favorable terms.

There are 3,500 acres of Redwood Timber land, new steam Saw-mill, general store, dwellings, logging railroad, water works, etc.

Satisfactory reasons for selling will be given to prospective purchasers.

Also, if desired in connection with the above, a lumber yard on the Bay of San Francisco, having superior facilities for shipping by rail or by water, and having a large and constantly increasing business.

For full particulars address

JOHN F. BYXBEE,
No. 22 California Street, San Francisco, Cal.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this journal, until further notice, $1.

Gundlach's Microscopes.

ERNST GUNDLACH

Would respectfully inform his friends and the scientific public generally that he, after having dissolved all connection with the "Bausch & Lomb Optical Co.," is continuing the manufacture of his well-known

MICROSCOPES and OBJECTIVES

On his own account, and that since March 8, 1878, all his articles have been and will be in future marked with his full name, "Ernst Gundlach."

He also takes great pleasure in announcing that he has made several novel improvements in both Objectives and Stands, and that his new arrangements enable him to make a considerable reduction in prices.

Send for circular. Address,

ERNST GUNDLACH,
Rochester, N. Y.

Smelter and Refiner.

A competent person is desirous of receiving the position of Superintendent of a Smelting and Refining Works. Can give satisfactory reference for ability to smelt all lead ores, refine silver and make market lead. No objections to go to the Territories. Address P. F. M., this office.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco.

HOME IN THE COUNTRY!

NOOK FARM.

Families wishing to spend the summer in the country will find this a cheerful home, and beautiful scenery of such endless variety as tempt to healthful exercise and recreation. We furnish good accommodations and an excellent table. Good fishing and hunting on the premises. Two trains from San Francisco, per Vallejo and Napa Valley Railroad, pass the Station daily.

Address, E. B. SMITH, Rutherford, Napa County, Cal.

MECHANICS' INSTITUTE.

13th INDUSTRIAL EXHIBITION.

SAN FRANCISCO, CAL., 1878.

The Managers have the honor to announce to the public that the Thirteenth Grand Exhibition of SCIENCE, ART and INDUSTRY, given under the auspices of the Mechanics' Institute, will open at the Pavilion on Market, Eighth and Mission streets, on

TUESDAY, AUGUST 13th, 1878.

Great and unusual attractions will be presented to visitors. Mining, Agricultural and other machinery will be in motion. Pacific Coast Manufactures, Minerals and products of the soil will be fully represented, beside many new and interesting novelties never before exhibited on this Coast. The

ART DEPARTMENT

Will be under the supervision of the San Francisco Art Association, a guarantee for excellence and completeness. Local Art will be specially represented, as also works of noted foreign artists, selected from the private galleries of this City. The

HORTICULTURAL GARDEN,

So popular heretofore, will be made still more attractive this year by the addition of many new features.

THE MUSIC.

Each afternoon and evening a first-class instrumental concert will be given by the best soloists and accomplished musicians of this City, with a daily change of programme of the best and most popular music.

No expense or pains will be spared by the Management that will add to the comfort or convenience of visitors.

Applications for space or information can be obtained from the Secretary, at the office, 27 Post street.

IRVING M. SCOTT, Pres't.
J. H. GILMORE, Sup't.
J. H. CULVER, Sec'y.

ST. CHARLES HOTEL,

SANTA CRUZ, CAL.

JOSEPH BLOCH, - - Proprietor.

KING ENGINE.

The Only SAFE BOILER.

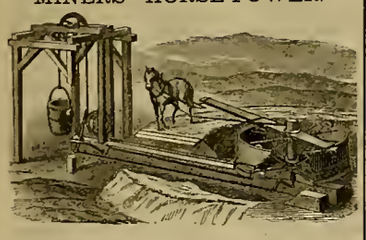
SAVES One-half the FUEL Consumed by Others.

The engine is adapted to all the various industries in which small power is required. The engines are FIRST-CLASS, and are made from two to twelve horse-power.

The smaller sizes are especially recommended for irrigating land, driving printing presses, or manufactories. The larger sizes are being extensively introduced in small quartz mills, where their economy of fuel and portability especially commend them. Send for circular.

REYNOLDS, RIX & CO., Sole Agents,
18 & 20 Fremont Street, San Francisco, Cal.

MINERS' HORSE-POWER.



This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS, RIX & CO.,
18 & 20 Fremont Street, San Francisco, Cal

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:

One man, per day	$3 50
One man, per day	3 00
Wood, 1¼ cords at $3	7 00
Cost of 20 tons	$13 50
Cost of one ton	67½

From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address:

Mining Share Market.

Last week we reported increased activity, particularly in some half a dozen stocks. Activity continued to increase through Monday morning, Union Con. running ahead of the other three favorites of last week, Sierra Nevada, Mexican and Ophir, as far as number of transactions is concerned. This is accounted for by the as yet unsettled claim that the recently reported strike in the Sierra Nevada was within the Union Con. line. Nothing definite has been reported from these mines, and, as a consequence, the rise in prices could not be expected to continue long. It did last longer, however, than was anticipated by some. It was not until Monday afternoon or Tuesday morning that a reaction made itself felt. On Thursday Union Con. reached $30; on Friday it was down to $24.25; on Monday it had risen again to $27, but on Tuesday it fell constantly, reaching $25.25. On Wednesday of last week Sierra Nevada was up to $38; since then it has been as low as $23.25, but on Tuesday, the 13th, it was $28.50, showing, however, a regular decline. More news from the mines is the one thing needful. A big strike was reported in the Julia, but as yet has amounted to nothing. The Bonanza mines have kept very steady. Mexican at one time seemed inclined to rise, but has finally shared the general decline. Perhaps the greatest interest in inside stocks has been centered on the Sierra Nevada, Union and Julia. When the developments made by the crosscuts in these mines become known, greater movements up or down may be expected.

A rise has occurred in Lady Washington and Benton, caused by favorable developments. This makes three very hopeful regions on the Comstock: the north end, the middle or vicinity of Julia, and the south end.

Among the outside stocks Bodie has created most excitement, showing as it has a constant rise. It is said now that the rise is well grounded, the reported developments in the mine being bona fide.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington, D. C.

FOR THE WEEK ENDING JULY 30TH, 1878.

RAILWAY TRACKS—Amos Bowman, S. F.
CAMP STOVES—Wm. B. Collier, San Diego, Cal.
AUTOMATIC WATER LIFTER—Abraham Gregg, San Diego, Cal.
GRAIN THRESHER AND SEPARATOR—Byron Jackson, Woodland, Cal.
HARROW HINGES—Hugh S. Jory, Salem, Oregon.
SAMPLE CARDS—Sigismund Kutnow, S. F.
GLOVES—August Hesthal, S. F.
OIL CUPS—Alden D. Kilborn, Oakland, Cal.
FIRE HYDRANTS—Samuel Rainey, S. F.

TRADEMARKS.

ALE AND PORTER—Burnell & Simpkins, S. F.

——The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

The Fair Season.

The following is a partial list of the coming fairs. We shall be pleased to add to it if readers will send us the dates and locations of their respective exhibitions:

San Francisco Mechanics' Institute, San Francisco, August 13th to September 14th.
California State Agricultural Society, September 16th to 21st, inclusive.
Oregon State fair, at Salem, October 8th to 18th, inclusive.
Nevada State Agricultural, Mining and Mechanical fair, at Reno, October 7th to 12th, inclusive.
Montana Agricultural, Mineral and Mechanical fair, at Helena, September 23d to 29th, inclusive.
Sonoma and Marin district fair, at Petaluma, September 23d to 28th, inclusive.
San Joaquin valley district fair, at Stockton, September 24th to 28th, inclusive.
Northern district fair, at Marysville, September 23d to 28th, inclusive.
Golden Gate district fair, at Oakland, September 9th to 16th, inclusive.
Napa and Solano district fair, at Vallejo, September 3d.
Monterey county district fair, at Salinas City, October 8th to 12th inclusive.
Siskiyou county fair, at Yreka, October 2d to 5th, inclusive.
El Dorado county fair, at Placerville, September 13th to 15th, inclusive.
Santa Clara valley fair, at San Jose, September 30th to October 5th, inclusive.
Stanislaus County Stock Growers Fair, at Modesto, October 9th to 11th inclusive.
Southern California Horticultural Fair, at Los Angeles, October 14th to October 19th, inclusive.
Southern California Agricultural Society's Fair, at Los Angeles, October 14th to October 19th, inclusive.
Plumas, Lassen and Modoc District Fair, at Susanville Lassen county, October 21st to 25th inclusive.

Woodward's Gardens were never more attractive than at present. Besides three lions already mentioned, six monster living alligators, several iguanas and a boa-constrictor have just been added. New stars are constantly engaged for the Pavilion exercises. Rates of admission as usual.

A New Mining Enterprise.

A company will shortly be incorporated in this city with a large capital stock, for the purpose of acquiring and working mineral land on the Pacific coast of the United States and adjoining countries. The company will mine coal, iron, silver, gold and all other minerals, sink petroleum wells, make coke and establish iron manufactories, build railroads where necessary, own and run steamers, and seek in every profitable manner to develop the resources of this coast.

A gentleman of life-long practical experience in the coal and petroleum regions of the East will devote his services to the company as President. A special feature will be made of coal, the safest and most lasting of all the minerals. Arrangements have already been made for the acquisition of valuable and accessible coal fields on the northern part of the coast, work on which will be commenced without delay. It is intended before New Year's to lay down coal of the best quality in San Francisco at a lower price than has yet been done. The company will arrange for the immediate construction of large and powerful steamers suited for carrying coal, merchandise and passengers, thus ensuring the shipping of their coal at a small expense.

A sufficient working capital for all purposes will render further calls on the shareholders unnecessary, and no assessment will be levied on the stock. Every facility will at all times be offered for full examination of the company's affairs by individual shareholders. Gentlemen well and honorably known both here and in the East are interested in the undertaking, and their names are a guarantee that the affairs of the company will be conducted in a perfectly fair and honorable manner. A large amount of stock has already been applied for in this country and in Europe.

This will be the strongest company ever organized on this coast, and offers unequaled inducements for the safe and profitable investment of capital, the stability and sure rise in value of real estate being here combined with the profits of mining and manufacturing, whilst the variety of operations to be carried on reduces the risk to a minimum. It is not intended to list this company on the Stock Boards of this city, its shares being offered as an investment, not as a gambling proposition.

Further particulars will be announced in these columns in the course of a few weeks.

San Francisco, August 15th, 1878.

To Mill and Mine Owners.

Having complete arrangements with competent and reliable parties in Washington City, by which we are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (with or without assistance by local attorneys), will see at once the great advantage of patronizing an establishment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally by a member of our firm, and satisfaction will be given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditch property, promptly attended to.

DEWEY & CO.,

Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS OFFICE, No 202 Sansome St., San Francisco.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

EXAMINE the accelerative endowment plan, as originated by the Mutual Benefit Life Insurance Co., of Newark, New Jersey. Assets, $30,533,429.94. Lewis C. Grover, President; L. Spencer Coble, Vice-President; Benjamin C. Miller, Treasurer; Edward A. Strong, Secretary; Bloomfield J. Miller, Actuary. Send for circulars to James Munsell, Jr., agent of insured, 224 Sansome St., San Francisco.

MODEL MAKER AND MACHINIST.—I. A. Heald, No 514 Commercial St., San Francisco, (fourth floor).

Take the paper that stands by your interests.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWELL—California.
A. C. KNOX—Pacific Coast.
C. N. WEST—Santa Cruz, Monterey and San Benito counties.
A. C. CHAMPION—Tulare, Fresno and Inyo counties.
W. D. WHITE—San Bernardino county.
J. W. A. WRIGHT.—Tulare, Fresno and Kern counties.
E. M. DENNY,—Oregon.
H. E. HALLETT.—Mendocino county.
G. W. MCGREW.—Santa Clara county.
RICHARD ALLEN.—British Columbia.
R. D. NUNNALLY.—Siskiyou County, Cal.
DR. W. G. ALBAN.—State of Nevada.

BUSINESS LETTERS should be addressed to the firm. Individual members are sometimes absent.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Gover Mining & Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the ninth day of August, 1878, an assessment (No. 37,) of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in gold coin or legal currency of the United States, to the Secretary, at the office of the Company, Room 8, No. 402 Front Street, San Francisco, Cal.

Any stock upon which said assessment shall remain unpaid, on Monday, September 23rd, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, October 21st, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

W. O. WILSON, Sec'y.

Office, Room 8, No. 402 Front Street, San Francisco, Cal.

Seaton Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Drytown Mining District, Amador County, California.

NOTICE.—There is delinquent upon the following described stock, on account of Assessment (No. 11) levied on the 20th day of June, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Thomas, W., Jr.	72	15	$1125 00
Thompson, W., Jr.	79	10	750 00

And in accordance with law and an order of the Board of Directors, made on the twenty-sixth day of June, 1878, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Company, Room No. 58 Nevada Block, northwest corner Pine and Montgomery streets, San Francisco, California, on Wednesday, the twenty-first day of August, 1878, at the hour of one o'clock P. M. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.

JOEL F. LIGHTNER, Sec'y.

Office, Room No. 58 Nevada Block, Northwest corner Pine and Montgomery streets, San Francisco, California.

Office South Comstock Gold and Silver Mining Company. Notice.—The annual meeting of the stockholders of the South Comstock Gold and Silver Mining Company, for the election of Trustees and the transaction of such other business as may be presented, will be held on Monday, the 19th day of August, 1878, at two o'clock P. M. of that day, at the office of the Company. Transfer books will be closed on Saturday, August 10th, 1878, at the hour of 12 M. of that day.

J. M. BUFFINGTON, Secretary.

Office—Rooms 3 and 4, second floor, No. 309 California street, over Aetna Insurance office.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Seventeenth day of July, A. D., 1878, an assessment, (No. 4,) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of said Company.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, A. D., 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the Tenth day of September, A. D., 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. J. W CLARK, Sec'y.

Office, No. 318 Pine Street, San Francisco, Cal.

Telegraph Copper and Silver Mining Company.—Principal place of business, City and County of San Francisco, California. Location of works, Gopher Mining District, Calaveras County, State of California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of July, 1878, an assessment of three (3) cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary, at his office, Room 2, 528 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 19th day of August, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Ninth (9th) day of September, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

I. T. MILLIKEN, Sec'y.

Office, Room 2, 528 California street, San Francisco, Cal.

Vigorit Powder Company.—Location of works, California City, Marin County, State of California. Location of principal place of business, City and County of San Francisco, California.

Notice is hereby given that at a meeting of the Directors held on the first day of August, 1878, an assessment (No. 1) of fifty cents (50c.) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room No 1, 109 California street, in the City and County of San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Thursday, the twelfth day of September, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the second day of October, 1878, to pay the delinquent assessment, together with costs of advertising and expense of sale.

JAS. W. BAKER, Sec'y.

Office, 109 California street, Room No. 1, City and County of San Francisco, California.

The "San Francisco Law Journal."

Published weekly, in 8vo size—like the California Reports—contains ALL the decisions of the California Supreme Court, soon as rendered, with syllabus and statements of facts; and also, important decisions of other courts of last resort. Two volumes each year, commencing September first and March first, with full index, so it can be nicely and cheaply bound.

Price, only $6.50 per year, or $3.50 for six months, strictly in advance. We print a "Legal Directory" on the *Journal* cover of lawyers' address cards, kept corrected for the year, for $3, or six months, $2 in advance. *Journal* and card both one year in advance, $9. Six months, both, $5. Remit by postal order or registered letter, specifying what date or number to begin. Back numbers furnished. Single numbers 25 cents each. Legal briefs and transcripts our specialty. Address

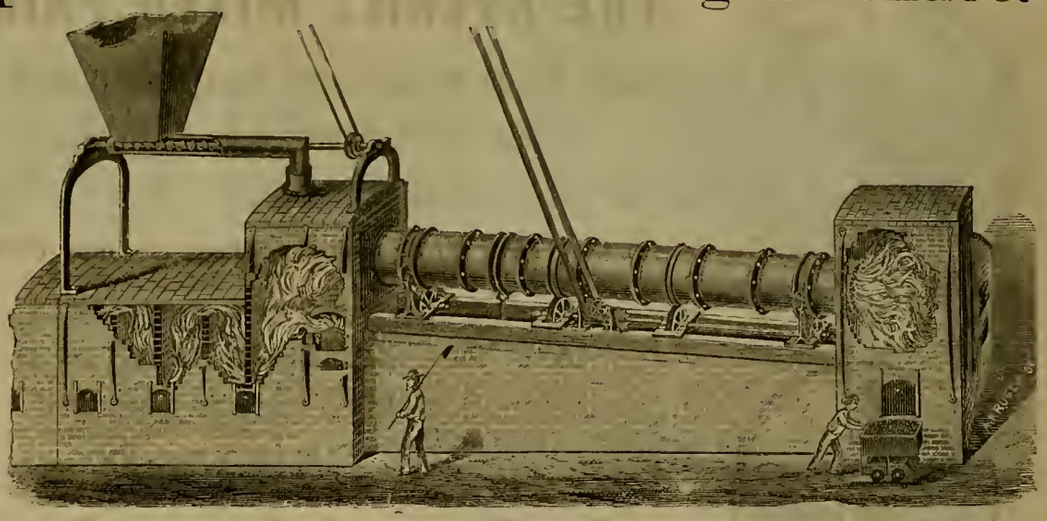
Howell's Improved White Roasting Furnace.



This cut represents the most improved construction of this unrivaled Furnace, the superiority of which, over all others as regards cost and capacity, as well as the economical and thorough oxidization and chloridization of ore, is now generally conceded.

In this Furnace, as covered by the Howell and White patents, are combined the three acknowledged requisites for the thorough and economical roasting and chloridization of ores.

First.—Continuous progression through and discharge of the ores from the furnace—while in the meantime they are, by being constantly showered through the heated air and gases within it, exposed in the greatest possible degrees to their reducing action.

Second.—Subjecting the ores to this showering process any length of time that may be necessary, according to the character of the ore, for its thorough reduction. In passing through the furnace it ordinarily falls about 1,000 feet, all the time in direct contact with the flame.

Third.—Increasing the heat on the ores as they are progressed through the furnace.

In this respect this furnace excels all others, as in none of them are combined all these essential requisites. It will chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade

The first cost, as well as the cost of operating it, is less than that of any other furnace of equal capacity.

It requires no especial skill in management that cannot be readily acquired by any one capable of conducting an ordinary silver mill.

We manufacture various sizes adapted to a five, ten or twenty-stamp mill, and will furnish plans by which any competent mill man can erect and operate it.

This furnace having the full or partial brick lined cylinder, embraces the devices covered by the patent to John Howell, as well as the original devices covered by the White patents. It has been erected and operated successfully at the following mines in California, Nevada, Arizona and Montana, viz: **Camanche, Jefferson, Leopard, Utah, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry, Independence, Endowment and Alice.**

At least ten of them are now in active and successful operation, in some cases reducing ores of the most refractory character.

These facts are a sufficient attestation of the merits of this furnace.

The undersigned, with Mr. John Howell, are the sole owners of the Howell patent, and they have perfected arrangements with him, and also with Mr. J. M. Thompson, who is owner of an interest in the White patents, and as such is possessed of as full and perfect rights and powers under the same as the patentee himself, by which they have acquired the exclusive right to manufacture these furnaces for the Pacific States and Territories. We hereby **caution** all parties against purchasing the same from any others but ourselves, or the said Howell or Thompson, as we shall prosecute all parties infringing upon the same. For particulars, price and terms, address

RANKIN, BRAYTON & CO.,

Pacific Iron Works, First and Fremont Sts., bet. Mission & Howard, San Francisco.

(OFFICIAL.)

THIRTEENTH INDUSTRIAL EXHIBITION

—OF THE—

Mechanics' Institute.

San Francisco, Cal., 1878.

The Managers have the honor to announce to the public that the Thirteenth Grand Exhibition of Science, Art and Industry, given under the auspices of the Mechanics' Institute, will open at the Pavilion on Market, Eighth and Mission streets,

TUESDAY, AUGUST 13th, 1878.

Great and unusual attractions will be presented to visitors. Mining, Agricultural and other Machinery will be in motion. Pacific Coast Manufactures, Minerals and Products of the soil will be fully represented, besides many new and interesting novelties never before exhibited on this coast.

THE ART DEPARTMENT

Will be under the supervision of the San Francisco Art Association—a guarantee for excellence and completeness. Local Art will be specially represented, as also works of noted foreign Artists, selected from the private galleries of this city.

THE HORTICULTURAL GARDEN,

So popular heretofore, will be made still more attractive this year by the addition of many new features.

THE MUSIC.

Every afternoon and evening a first-class Instrumental Concert will be given by the best soloists and accomplished musicians of this city, with a daily change of programme of the best and most popular music.

No expense or pains will be spared by the management that will add to the comfort or convenience of visitors. Applications for space or information can be obtained from the Secretary, at the office, 27 Post street.

IRVING M. SCOTT, President.
J. H. GILMORE, Superintendent.
J. H. CULVER, Secretary.

E. G. DENNISTON, - - - - - - - - PROPRIETOR

Hotel, Restaurant, Plumbers', Gunsmiths', and all kinds of metal work plated in the most durable manner. A large stock of new Plated-ware and Cutlery for sale at Manufacturers' prices.

THE AVERILL MIXED PAINT,

Prepared Ready for Use, is the Best, Most Durable, Beautiful and Economical Paint Known.

As is proven by the numerous Medals received over all other Paints, as well as by thousands of testimonials from those who have used and thoroughly tested it.

It is of Pure White and any Shade or Color Desired.

AS A HOUSE PAINT

It is the most perfect substance known, possessing unsurpassed beauty, great brilliancy of color, adhering firmly to the wood, and giving the richest, most agreeable and uniform tints.

It is equally as good for inside as outside work; over old work as well as new; in fact where any Paint can be used the AVERILL PAINT will be found superior to any other.

Houses painted with it are distinguishable for years by their *superior brilliancy of finish*, over those painted with any other paint.

Our Wagon and Machinery Paints

From the finest Vermilion, to the more common and cheaper colors, are *specially fine*, and being ready mixed, meet the wants of the public completely. Every person owning a wagon, or any kind of machinery, should occasionly give them a fresh coat of paint. It would add to the durability and appearance of the articles a hundred times its cost.

Our Metallic Paint

Comes the nearest to being *actually* Fire Proof of any Paint ever made. For *Tin Roofs* it has no equal, it being entirely impervious to air or moisture—rust or corrosion is impossible, while its use on shingle roofs not only fills up the cracks and prevents the shingles from warping, so as to preserve the roof and prevent its leaking, but its *fire proof* qualities are such, that a roof thoroughly coated with it is nearly as safe from fire as if made of *iron*. This feature, together with its *cheapness*, makes it most desirable for warehouses, bridges, *mining buildings*, and for all purposes where durability and fire proof qualities are desired.

Ask your dealers for it and take no other. Sample Cards of Colors and Price List mailed free on application to

California Paint Company,

No. 329 Market Street, San Francisco, Cal.

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,

(Of the San Francisco *Evening Post.*)

This volume is now ready. It is a large 12mo of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loop, at Tehachape Pass, on the S. P. R. R.; Yuma, Prescott, Phœnix, Florences, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains. Calabazas, in the valley of Santa Cruz; Corrunnacion Peak, the Ariave Valley and the ruins of Casa Grande.

Also, numerous other engravings of mines and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the McCrackin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for $2 each.

HINTON'S NEW MAP OF ARIZONA,

Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, $2.50 each; in covers, $1.50 each. For sale by

DEWEY & CO.,

Assessment Notice—Vigorit Powder Co., Jas. W. Baker Secretary, S. F.

This paper is printed with Ink furnished by Chas. Eneu Johnson & Co., 509 South 10th St., Philadelphia & 59 Gold St., N. Y.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS,

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive.

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. ☞Triple Force Caps and all Grades of Fuse.

BANDMANN, NIELSEN & CO., San Francisco.

PACIFIC MAIL STEAMSHIP CO.

The Company's Steamers will sail as follows, at 12 M.:

CITY OF TOKIO.....August 31st.
For YOKOHAMA and HONGKONG.

GRANADA.....August 19th.
For Panama and New York, calling at Acapulco, San Jose de Guatemala, La Libertad and Punta Arenas.

Tickets to and from Europe by any line for sale at the lowest rates.

CITY OF SYDNEY.....September 2d, at 12 o'clock, noon, or on arrival of the English Mails, for HONOLULU, AUCKLAND and SYDNEY.

$10 additional is charged for passage in Upper Saloon.

DAKOTA.....August 20th.
For Victoria, Port Townsend, Seattle, Tacoma and Olympia, connecting at Tacoma with Northern Pacific Railroad for Portland, Oregon.

Tickets must be purchased before 11 A. M. on day of sailing, at Wharf office.

For freight or passage apply at the office corner First and Brannan streets.

WILLIAMS, BLANCHARD & CO., Agts.

ASSAYING 604 Washington St., SAN FRANCISCO. TAUGHT.

The Kendall Quartz Mill.

The engraving on this page represents an improved quartz stamp, recently invented by Stephen Kendall, of Jackson, Amador county, and which is now being introduced to the mining public. The improvement consists in a novel construction and operation of the cam which serves to lift the stamp, and in the employment of a peculiarly-shaped tappet, which is secured to the stamp stem, so as to revolve with it in a horizontal plane and be acted upon by the cam to raise the stamp. The stamp stem is made square at or near the top, to receive the driving pulley, and this form, or an equivalent feather, allows the stem to rise and fall without deranging the action of the pulley. The cam is mounted upon a cushion to prevent jar, and the mortar is fitted with sockets, so that the battery frame may be supported directly upon it. The stamp is raised by the tappet rising on the incline or cam, and as it drops off the cam, a grinding action is produced by the rotation of the stamp until it again rises. By this means, both a crushing and grinding motion are produced in the stamp.

The mortar is constructed in such a manner as to accommodate one stamp only, and having one or more discharge openings, in which are the screens. The upper portion of the mortar is curved inward, and in the rear upper portion is formed the feed hole, through which the ore is fed. Attached to, or formed on the sides of the mortar, are the sockets, into which are stepped the lower ends of the vertical frame posts, which are held in place by the straps or bands secured by bolts, as shown. A timber across the top joins these frame posts together, so that all the frame work necessary to guide the stamp stem and support it is attached to the mortar.

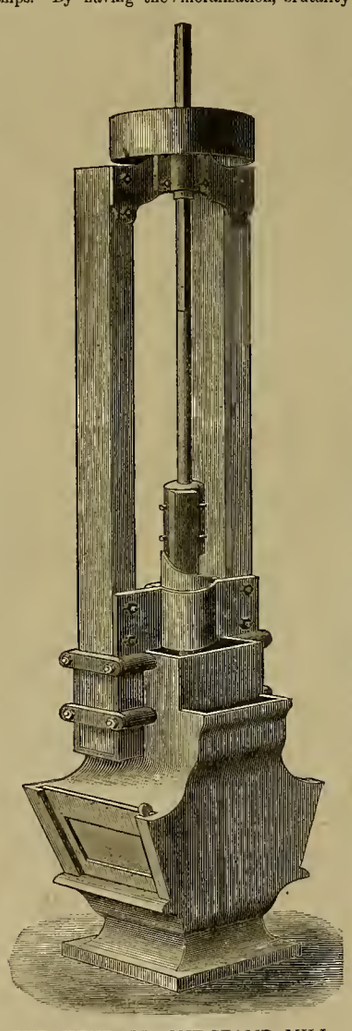
The stamp, shoe and die are the same as in any ordinary battery. Across between the vertical timbers and above the mortar is placed a guide or girt, which is of cast iron, and through which the stamp stem plays. On one side of this girt is formed a curved projection, which has a curved slot formed in its upper surface. In this curved slot rests a horizontally-placed incline or cam. This cam has its lower end made on a horizontal plane, so that it will rest in the bottom of the slot in the projection. In the bottom of this slot, or in the bottom of the cam, is a rubber block or bed, which forms a cushion for the cam, so that when the tappet strikes it in rapid revolution, no jar will be experienced. A spring may be used instead of the rubber, if desired.

Upon the stamp stem, at the proper point above the girt with its cam, is secured a tappet, having a beveled flange or cam-like projection on its lower edge. When the stamp stem is rotated by the pulley on its upper end, this flange in the tappet engages with the cam, and by moving up the incline, raises the stamp. As soon as the highest point in the cam is reached, the flange on the tappet leaves the cam and the stamp drops, which operation is repeated as the stamp stem is revolved. In order to allow the vertical motion to the stamp stem necessary in this device and at the same time admit of its rotary motion, the upper part of the stamp stem is made square, or has a feather formed on it. In the present instance, it is shown as square in shape and passing through a collar, journaled in the upper cross timber.

Attached to this collar is the horizontal pulley through which the square or fastened end of the stem also passes, the hole through the collar and center of the pulley being formed to correspond with the shape of the stem. As the pulley is revolved by the belt, the stamp stem, stamp and shoe will be revolved, and at the same time a vertical motion of the stamp stem is possible, so as to admit of the flange on the tappet rising up the incline of the cam on the girt timbers and raising the stamp.

By this method of construction and operation it is possible to obtain a very rapid stamping motion by a correspondingly rapid revolution of the driving pulley. Moreover the act of crushing is supplemented by a grinding motion of the shoe on the die, since, when the flange on the tappet falls off the cam and the stamp drops, the stamp has a rotary grinding motion on the quartz or ore under it, until it is again lifted by the flange rising on the incline or cam as described.

The stamp thus alternately grinds and crushes, and is therefore capable of greater crushing power than when a drop alone is used. With this device the number is enlarged to construct a single stamp battery for prospecting purposes, which may be run by water, steam, horse or hand power, and which will be more efficient in its action than the ordinary appliances used for the purpose. The principle may also be applied to large mills where a number of stamps are used, by using a suitable line shaft and gearing for the stamps. By having the front and both sides of the mortar made open, a large discharge or screen surface is gained, and the mill may be used for either dry or wet crushing as desired. The stamp mill may be made in sections for facility in transportation. Where large mills are used, it is proposed to have a mortar for each stamp as described, so that each stamp may be operated from the line shaft independently. The whole mill need never then be closed down for cleaning up or repairs. By throwing a single stamp out of gear, the tappet may be raised, new shoes or dies put in, the mortar cleaned up, etc., without interfering with the remainder of the mill. In a large mill of this kind, having a number of these stamps, the owners might dispose of each stamp separately in case of the enterprise not proving profitable, as each stamp then forms a separate mill. As mines are being developed, one stamp at a time may be added to the mill as the capacity of the mine increase, whereas by the present system, at least five stamps must be added at once. By the peculiar crushing and grinding motion of this mill, and its capacity for rapid crushing and grinding, it is claimed that the single stamp has as much crushing capacity as a five-stamp battery of the common construction, where a drop only is used. The hight of drop may be regulated in the usual manner by means of the tappet.



THE KENDALL ONE-STAMP MILL.

By the method employed of placing a rubber band or spring under the tappet, a great deal of the jar is avoided, which it has been impossible to overcome by the old method. The grinding action of the stamp is very advantageous in crushing the quartz, since as soon as the blow is struck and the quartz crushed under the stamp, it is immediately ground finer, and any particles of gold under the stamp are brightened or polished, so as to put them in proper condition for perfect amalgamation.

An experimental mill of this character has been run some eight months with great success, and several of the mills have been constructed at the Pacific Iron Works in this city and set at work. The operation of the mill has excited favorable comment from a number of milling experts, and as it has the crushing action of the stamp and grinding action of the arastra combined, its crushing capacity is greater than one would suppose. Messrs. Rankin, Brayton & Co., of the Pacific Iron Works, have, in addition to the mills sent off to work in the mines, built one which may be seen in motion at their works in this city, and those interested in such devices are invited to call and examine it.

Have a Care Ye People!

If we have not now reached the sub-cellar of infamy in the administering of public offices, may God help the people! Can the structure of official corruption and administration possibly extend farther down into the depths of utter demoralization, brutality and heinous crime? It is hard to conceive it possible. It will be hard to imagine a thought and action which lays a stronger hold upon the corner stones of perdition, than those which the last week brought to light.

The public administrator of Sacramento county, a man chosen according to the law, to act as guardian over the property of the friendless dead, stands the confessed planner, promoter and purchaser of the murder of a lone old man, in order that he, the public administrator, might get possession of the old man's property, and gorge himself with fees and stealings. With cool persistency, they labored to accomplish their hellish object—this public administrator and his hired assassins. It began in a joke, so his story goes, in this wise: His low-lived associates would rally him by asking, forsooth, what percentage he would allow to those who put out of the way friendless rich men that he might "administer their estates." A "commission" on the results of a murder! California, cursed with "commissions," knew no such ghastly commission as this, before last week. Well, the joke lingered in the thought of the public administrator. About him gathered men who boasted of their foul hutcheries, and who "would kill any man for $100." The idea did not displease this public administrator, this representative of the sacred honor of the people. The joke called forth the wish; the wish the thought; the thought the plan, and the plan pursued with fiendish calmness and ingenuity, ended at length in the brutal murder of a friendless old man, in broad day light, on his lonely ranch beside the turgid waters of the Sacramento. Did the public administrator strike the blow or fire the shot which clave the old man's skull as he sank among the rushes on the river bank? No. But he went out at nightfall along the river to meet his hired murderers, "whistling a song," as he drove along in his buggy, that they might know him; and as he met his bloodstained hutchers, this public administrator, embodiment of the people's care for the discharge of sacred trusts, bestowed this devilish plaudit upon his servants: "Boys, you have done pretty well. I would like to have had a band in it myself. I am going to stand the oysters on this!"

Oh, shame! Shame upon humanity that it could conceive a thought, mature a purpose and promote a deed like this we have described. And yet is it wholly unintelligible? Does it come like a storm from a clear sky? We grieve to say it does not. Is it anything more than the perfect fruit of an evil growth of corruption in public offices, the fetid odor of whose blossoms has often warned the people of its progress? What was the seed whence has sprang this evil growth? It is the idea that a public office is a thing to be employed for the advantage of the officer, and oblivion to the fact that an office is in reality a trust from the people to be discharged for the people. Standing at this point of view it is easy to follow the results of the growth of this idea. It begins with the greedy strife for office, because of its emoluments. Its first leaves are the petty stealings of policemen, clerks and minor civil officers. Its trunk, perhaps, is the appropriation of millions of dollars to personal aggrandizement, under the guise of carrying out vast internal improvements. It has branched and blossomed, as we have said, in the hundreds of malfeasances, embezzlements and perversions in government contracts, in savings banks and the like. Its natural fruitage is the sacrifice of human life, when life alone stands between it and its accomplishment.

Does the murder at Sacramento seem less startling when it is read in the light of the lurid glare of the perdition which is wide spread in our public service? By no means. It has a much darker and deeper significance when thus interpreted. It must be that the people needed this ghastly spectacle before it would fully perceive the evil tendency which is so alarmingly extending. Will it be heeded now? We know nothing of the circumstances attending the choice of this man in Sacramento county for the important trust of public administrator. We know not what party nominated him, nor do we care. The practical inquiry which is now pertinent is this: Was there nothing about the man or his surroundings which would have forewarned the upright citizen against trusting him? Did he grow all at once into association with professional criminals? Was he so upright a man that any citizen would have entrusted to him his estate without a doubt of his honest management of it? If there was a doubt of any of these things, then he was not the man to name for a public trust, not the man to receive the people's votes. It comes to this, and this only. The safety of the people's life and the people's property, the honest administration of the law, depend upon the choice for office of men about whom hangs no suspicion of evil, and whose life, surroundings and companionship are such as would warrant the imparting of individual as well as public trusts. This is the only safeguard which remains for the purity of our public service. If this lesson be learned in this State from the events of the last week, then the lone old man on the Sacramento will not have died in vain!

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Northern Belle, Aug. 17th, $5,500.16; Ontario, Aug. 9th, $3,050.83; Aug. 10th, $2,982.60; Aug. 12th, $6,117.65; Aug. 13th, $6,121.28; Aug. 14th, $2,954.85; Aug. 15th, $5,823.45; Silver Reef, Aug. 9th, $1,202.32; Aug. 13th, $9,221.98; Locke's Mills, Aug. 10th, $800; Hampton Mine, Aug. 15th, $600; Eberhardt & Aurora, Aug. 6th, $8,114.64; Aug. 15th, $7,225.19; total for August, $15,339.93; Tyho Con. Aug. 14th, $4,848.92; Aug. 16th, $9,514.74; total to date, $38,245.78; Standard, Aug. 17th, $20,439.42; Silver King, Aug. 19th, $10,000; Wenhan, Cortez District, Aug. 14th, $5,544; Star, Cherry creek, Aug. 14th, $2,500; Bodie, Aug, 15th, $31,400; Aug. 21st, $16,000; total for August, $431,000; Black Jack. $4,162.39; Graham, Silver City, $7,336.14; Monarch, Atlanta, $4,425; Independence, Aug. 13th, $7,976; Richmond, Aug. 14th, $13,938.78; Indian Queen, Aug. 14th, $4,504.58; Extra, Shasta county, $2,450.80; Hackherry, Aug. 12th, $11,000; Aug. 19th, $5,000.

DURING the week ending August 13th, 43,552 pounds of sulphur and 24,570 pounds of quicksilver was shipped by rail from Calistoga to San Francisco.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Vancouver's Island, B. C.

As promised in your last issue, I now give your readers an account of my travels over the Vancouver Island, when examining quartz veins, and may say that, after suitable preparations, we proceeded on board the comfortable little boat *Cariboo Fly*, from the city of Victoria, which, as you may know, is situated on the southeastern and inner side of the island, and then steamed northerly in serpentine passage between many very interesting and beautifully picturesque isles, until, favored by the Captain's courtesy and an Indian's canoe, we landed on an open beach near the Qualicum river, about 45 miles north of the celebrated coaling town of Navaimo.

Thus far it was a pleasant dream and congenial voyage of surpassing beauty, as well as instruction in the various rock formations of the many islands; but we had to awake to the really earnest toils of life, and brace our minds and muscles for three weeks' violent exercise, traveling through dense undergrowths, over hill and dale, and patient endurance of the most miserable foods, bread baked in a frying pan and fat bacon.

Whilst the four Indians were equalizing and arranging their packs, which contained our blankets and sufficient food for the double journey, I strayed aloug the pebbled shore to see what kinds of rocks had been washed by the river from the interior, and was somewhat disappointed to find them of igneous origin. We started at about one o'clock for crossing the island to what is called the Alberni canal, or more properly, the navigable head of the Barclay sound, an extremely beautiful and well-wooded valley, which forms that deep-water inlet from the western, or outside coast, of Vancouver's Island. The first day's travel was by the Government trail, which, though much obstructed by this year's undergrowth and fallen timber, was not difficult for pedestrians, and after passing about half over the island; we camped by a splendid sheet of water, about six miles long hy a half mile wide, and which, excepting at the Qualicum river outlet, is surrounded hy steep mountains.

The pebbled shores of the lake also exposed various igneous rocks. We made an early start on the following morning, and after a hard journey around the north side of the lake and over the mountain beyond, in which a young Indian fairly broke down, at 6 P. M. we reached the Alberni canal and some kind-hearted, hospitable farmers, located upon a horizontal region, about five miles in diameter.

This flat district will probably yield coal, as the proper indications are in some places exposed hy the washings in the gulches. The monntain passed over and those surrounding this coal measure are, however, too igneous for coal or vein formations. Notwithstanding this, I was informed that no less than 12 parties have left Victoria at different times for the prospection of this mountain for ciunabar, but I saw nothing there or *en route* having the least similarity to that mineral. There was, however, a great deal of very hard red jasper in places, but always in the wrong country rock, and therefore could not he regarded as being indicative of the mineral of mercury.

Our next day's journey was hy an unstable canoe over the deep waters of the Barclay sound, ahout half way out toward the ocean, to the mouth of the Ashlet river, a rapidly falling and powerful, but unnavigable stream.

Having supplied ourselves with another lot of Indians in place of those broken down, we proceeded up the 32 miles loug, and terribly rough canyon of this river, guided by "hlazed" trees, across innumerable slopes of side-hills and tributary valleys, through almost everlasting confusions and profusions of undergrowths, as ferns, mosses, the poisonous and prickly plant, appropriately named "devil's club," and various wild fruit trees, which frequently, by interlacing and spreading over three or four deep of fallen timber, renders travel so uncertain hy day as to be a "caution to snakes" and even hears; whilst the living forests of timher were so densely thick that their entangled hranches often returned such unnatural groanings to the wind as to prevent sleeping at night.

These are the general natural characteristics of this country, so different to the mineral States of U. S. America, where you can ride almost anywhere, and to make it even worse, we had a pelting raiu which rendered the undergrowths detestable, on the third day's travel up this valley aud the sixth and last of our journey to the source of the river and our destination, which I named Bear Basiu. It may be also stated that a prospector cannot judge of either distant or close lying rocks by appearance, as they are almost invariably covered with moss or a very thin encrustation of vegetable growth, so that the hammer must he used continually for breaking, to expose the interior and true character of the stone.

In this profusion of vegetation there is exceedingly little for men or animals to eat, as game is either scarce or too much concealed, and grass, for some reason, is substituted by the more persistent and apparently useless mosses, ferns, etc., which prevail over every available surface.

Bear Basin and the Ashlet river may be said to resemble a large spoon with a long crooked handle, running westerly, the margin of which, particularly at the upper end or hasin, is composed of steep mountains, 4,000 or 5,000 feet high, which receive the snows of winter as reservoirs, that dissolving in summer, form several waterfalls, which sink beneath the gravel debris of the basin, to reappear in forming the sonrce of the river.

The rock formations of the margin of this river and basin do not materially differ from those described before, only in showing occasional patches of trachyte, with the more general bed of trap.

In reference to the so-called qnartz veins I went to examiue, which were said to lie in granite and slate, you may readily imagine them worthless in the igneous rocks described; they were really just as many inches wide as feet stated, and running very irregularly but a few feet in length, and if they were found good it would have required at least $30,000 to make a road for delivering a suitable mill for working the mines.

Passing the matter of vein mining, I found more sulphuret of iron disseminated through the bedrock, than I have ever seen elsewhere; and an immense deposit of gravel in this basin and the upper and adjoining parts of the river, which had been concentrated and deposited at remote periods of time, by the heavy washings of gradually receding ocean waters which then played upon the declivities of these mountains, and we located for the company 40 acres of the basin and 2,500 feet down river for hydraulic and ground sluice mining, by the unusually convenient and abundant falls of headwaters and the river's outlet for discharge of tailings. I have rarely seen a more interesting gravel deposit, and as the approaching section of the ancient bottom of the river channel may be easily and cheaply proven by "ground sluicing" for ahont $2,000, I strongly advised its accomplishment, and as it is now heing executed, it is very probable that profitable results will be attained; and if so, not only will there be a long run on the river, but a large and very valuable property heyond for future "hydraulic" mining.

Be this as it may, 60 persistent pioneering Chinamen have been working the lower half of this same river for years, by much more laborious "wing-dams" and "crevicing," where they are evidently doing well.

All the leading streams from the interior of the island have produced gold. Before leaving this region I climbed to the top of the very steep mountam margin of the Bear hasin, where I discovered a small lake and a river's headwaters, which ran southerly, hut neither was marked on the map.

Heavy ranges of monntains lie southeasterly, as a kind of hackbone, where minerals may be fonnd if the rocks are congenial.

Very large snow-capped mountains lie near the north end of the island, whence the waters of the river, after forming a large lake three miles long, runs into the Alberni canal and Barclay sound.

Trails should be cut to these enticing mountains by government, so that those inclined for exploration may have au opportunity for their examination, as so little is known of the lofty interior, and hy far the most interesting portions of the island for minerals.

I was shown a very good specimen of mineral bearing blue carbonate of lime, which had been taken from a hill in a northerly bearing inlet, lower down and near the mouth of the Barclay Sound.

It should be stated that the large lake alluded to can be reached by rowing up the river from Alberni, in canoes; and it is probahle that a much shorter trail may he made from thence to the said northern mountains than from the ocean shores.

After spending about six days on and around the ground, examining, etc., we had to retrace our path homeward which was much less difficult and more speedy, for the reasons of having less weight to pack, more down hill, and a desire to get out of the woods. And on reaching the salt water, on the second day, sailed up the Sound the same evening hefore a strong wind and heavy sea, in a weak and light canoe, as guided through the drenching, dangerous spray hy an Indian and his squaw, when we momentarily expected to have to swim for our lives, but arrived safely at Alberni ranches and a large encampment of Indians who were arranged in a circle, greatly enjoying the excitement of gambling in clamorous accents at the sound of a rudely-extemporized drum.

After appreciatiug a supper from the Indian's hroiled salmon and a good night's rest in the farmer's straw, we hreakfasted early and started across the island with the determination to reach the other side that night; and although our ardor was much dampened hy a day's rain and no canoe at the right end of the Horn Lake, we reached Uncle Tom's camp just after dark and dried our dripping garments by the fire hefore turning into our wet hlankets.

Worse fare than ever, for ours was all eaten; and all that Tom and his better half, squaw or clntchman could offer, was a choice hetween salt clams smoked and dried until as tough as leather, on a continuously suspended string, or some stewed herring spawn just cleaned from seaweed and filth as taken from off the shore, where it accumulates at the proper season in enormous quantities.

They however did all they conld, none could do more, and "all is well that ends well!" You will think it strange traveling, and although I have made two trips on horsehack, the one in Nevada 30 days, and the other in Colorado 35 days, I enjoyed this better for its novelty; and after all was astonished to find that I had wasted only from 202 to 201 pounds.

There are two things I must not pass over without honorable mention, which are first the "chinook" or classical language of these various tribes of Indians and white inhahitants, and secondly the fact that we traveled in perfect safety with and through Indians who were fully armed when we were not. This language was, as you know, introduced for trading purposes hy the Hudson Bay Co., and it has now become generally known by the old Indians, English, and even the Chinese, whom the Indians despise and ridicule at every opportunity.

I think the convenience for explanation hy this jargon has greatly aided the civilization of these men, and peaceful occupation of this vast county hy such an exceedingly small community.

We slept soundly, and boarded the welcome *Cariboo Fly* in the morning on her upward trip to Comox, so as to use her as a boarding house until she returned to repeat the delightful trip through the labyrinth of waters and woods to Victoria.

J. S. PHILLIPS.

Changes and Improvements at Eureka.

EDITORS PRESS:—Having returned to this camp after an absence of two years, it may be of some interest to your readers to note the changes and improvements that have taken place in the meantime. Two years ago the Richmond was the only paying mine in the county. Other mines, that are now productive, were then unworked, and all, even the Eureka Con. were levying assessments. Since then, the number of men employed in mining and the products accruing from their labors have fully trebled. New enterprises have sprung into existence, with an energy and intrepidity characteristic of the place, and with every prospect of success in the near future. This may well he said of the Albion.

The Albion

Joins the Richmond on the northwest. It was located last March. There are four locations, each 1,500 feet long by 200 feet wide. At the time of locating, the locaters were foremen in the Richmond, but they immediately resigned their positions and went earnestly to work to develop their own property. Complete hoisting works have been erected; the shaft has been sunk 335 feet, and a drift is now being run across the ledge. The ore formation has already been cut into, and early developments are confidently expected. The Albion is on the great Ruby Hill lode. It is the opinion of miners and experts that the ore bodies found in the Eureka Con. and Richmond mines extend northward into the Albion ground, and, in consequence, the property is considered of great value.

The Richmond.

So much has been said and written concerning the Richmond within the past year, that it will not he necessary for me to go into details. As soon as it was known that the result of the "big lawsuit" was unfavorable, the Richmond managers, having been estopped from working their principal ore body, directed their attention to prospecting in other parts of the mine. Drifts and winzes were run in all directions. Ore was found at every point. So extensive have been the developments, that, notwithstanding the adverse result of the lawsuit, the Richmond stock commands higher prices now than ever before. Nor are those prices unduly inflated. They are based upon real merit. They are sustained by the appearance of the mine, and hy the returns and dividends during the past year. The ore yield is nearly 200 tons daily, enough to keep four furnaces in constant operation.

It is now two years since the Richmond shaft was sunk to its present depth, which is 900 feet. Since then all the ore extracted was taken from above that depth. The Managers feel that productive as the old levels have been, they are not exhaustless, and in order to keep up the present production, it will be necessary to sink the shaft deeper and extend the workings downwards. With this end in view a large air compressor has been ordered.

Eureka Con.

The Eureka Con. is *par excellence* the mine of the district. It occupies the most central position on Ruby Hill. It is worked to a depth of 1,000 feet. The present daily ore product is 240 tons, which is extracted on all the levels from the 11th upwards. The incline shaft has recently heen sunk to the 12th level, a station chambered out, and a drift started for the ledge. There can be no douht that the ore continues down to the 12th, as it has already heen prospected nearly to that depth from the levels above. The mine is supplied with all the modern appliances for deep mining, Burleigh drills, air compressors, and machinery powerful enough for continning the workings to a depth of 1,500 feet.

Excluding the honanza mines, the Eureka Con. has paid more in dividends during the past 12 months than any other mine on the Pacific coast. There are 50,000 shares; a monthly dividend of $3 per share has heen paid. This aggregates the grand total of $1,800,000. This is surely a good showing. This good showing is to be mainly attributed to the superior management of Mr. Henry Donnelly, and to his skill in selecting competent assistants. As soon as Mr. Donnelly was appointed superintendent he sent for a Cornish "captain" and made bim foreman of the mine. The gentlemanly "captain" is an old miner, a man of practical experience in underground workings. At that time the mine was in a bad fix. It had previously been worked with a view to getting out all the ore in sight and easy of access, regardless of consequences. Accidents were of frequent occurrence. There was no regularity, no system adhered to. It took some time to put the mine in order. Then the lawsuit came; it, too, interfered a good deal with operations. Since its settlement everything has gone smoothly. There is some local feeling manifested against Mr. Donnelly for employing almost exclusively aliens in working the mine. But the merchants in Eureka and the stockholders have no cause for complaint. As a class, Cornish miners are sober, industrious and intelligent. Their employment in the Eureka Con. mine has resulted in complete success. Every month the dividend comes as regular aud as surely as night follows day.

The K. K. and Phenix.

Owing to an accident to the machinery the K. K. is at present shut down, on which account your correspondent was unable to gain admission to it. The Phenix joins the K. K. on the south. This company, after a rest of nearly six years, are making active preparations for a fresh start. They are grading and building roads, erecting new hoisting works and machinery. The machinery will be placed on the old shaft. The shaft is 400 feet deep. As was to be expected the timbers have decayed in many places, and it will require a good deal of repairing before it will be fit for work

The mine has been partially prospected through the K. K. Ore was found in several places. Six years ago when the Phenix was working before, the peculiarities of this district were little understood hy the miners. Experience has taught us many things since. The old Phenix workings do not extend far enough to the eastward. The old levels will soon be renovated and prospected anew, and I have no doubt ore in large quantities will be found.

In my next I will give an account of the principal mines on Prospect mountain.

W. H. P.

Eureka, Nevada, August 9th.

Exploitation of Mines.

Translated for the MINING AND SCIENTIFIC PRESS from LE CHARBON.

We translate the following from the journal named above. It is made up from exhibits, etc., appearing at the International Exhibition at Paris for 1878.

In the working even of mineral veins marked progress has been made, owing to a more extensive exploitation, characterized by a better choice of methods, and their perfection for the most part.

In the coal mines, particularly at the time of the great price of coal, they attacked neglected beds or those hitherto insufficiently worked. In the little beds they accomplished a complete removal with the least possible deterioration of the matter to be extracted, owing to the fact that the worked out parts of the mine were filled in, setting and caving, as well as explosions were avoided, and all the precautions could he taken for the security of the men and the purity of the product obtained.

This more thorough exploitation of the mineral riches has produced an amelioration of all the details of subterranean transport. Everywhere have been adopted cars better studied, often of iron to augment their capacity, with given exterior dimensions, and of ways established with stronger rails, often joined with fish-plates (*eclisses*) fixed upon larger cross ties.

In short, in all the coal mines have been established steam or compressed air engines for working interior shafts, inclines and horizontal roadways hy cables or chains, hy means of which the cars are drawn from these interior shafts to the coal bins often very distant. At the mines of Cessons, they have introduced small locomotives in the mines, and at Blanzy they are about to construct a locomotive run hy compressed air, which will not vitiate the air of the works.

The hoisting machines have become more strongly built of late, to fulfill the greater duty demanded of them, owing to the further development of the mines, which has greatly increased their depth.

The system of expansion was adopted for the powerful hoisting machines at Blanzy for the first time; since which the system has extended itself, and ingenious mechanisms have been invented to perfect it.

At the mines of Epinac they have substituted for the ordinary hoisting arrangement, with cable and drum, the system called atmospheric. In this system the guides are replaced by a tube of large diameter, reaching like it from top to hottom of the shaft, and in the interior of which moves a piston, carrying at its hottom the charge to he raised. A vacuum is made above the piston, and the atmospheric pressure from below

MECHANICAL PROGRESS.

The Steam Wagon Contest in Wisconsin.

We have alluded formerly to the ceatest in Wisconsin fer the $10,000 prize offered by the Legislature for a successful steam road wagon. The trial was made a few weeks since, and the local papers are well filled with roports of the trials. We select important points. Two machines were entered for trial, the *Oshkosh*, owned by Schomer & Farrand, of Oshkosh, and the *Green Bay*, owned by the Cowles Bros., of East Green bay. The start was made from Fort Howard, at noon of the 16th inst. When the *Green Bay* had emerged from the city limits it broke down, and was sent back to the shop for repairs. The *Oshkosh* kept on its way, reaching Appleton, a distance of 32 miles, at 8 P. M. Leaving Appleton at 9:30 the following morning, Neenah was reached in time for dinner, and the people of this little "Flower of the Fox" were treated to an exhibition of speed on the principal streets of the city. From Neenah to Oshkosh is about 14 miles, and the machine made the trip in two hours, from 1 to 3 P. M. At Oshkosh the Green Bay machine was found. It made good time on a flat car over the Chicago & Northwestern railway, and beat the Second City invention by several hours. A trial of speed was in order. The *Green Bay* was speedy, but it couldn't run a mile without stopping, and the Oshkosh wagon shut it out in two straight heats, in 4.36 and 4.41. Finally, the *Oshkosh*, in chargo of the inventors, accompanied by Commissioner Olin, arrived in Madison, having made the trip from Fort Howard, 201 miles, in 33 hours and 27 seconds, official time. The time allowance given by law, five miles an hour, was 40 hours. The *Oshkosh*, therefore, beat the official time 6 hours and 33 minutes. This machine has throughout hauled a wagon weighing 3,500 pounds. The weight of the machine alone is 4,800 pounds, and with water and coal for eight miles, 6,600 pounds. It is a handsome affair, neatly and simply made, and appears calculated to do any amount of work. The engineers report no breakages on the trip, no runaways from scared teams, and not a bridge plank disturbed; while most of the roadway has been hard to travel, being heavy sand and gravel. The fastest time made by it was between Johnson's Creek and Fort Atkinson, 57 miles in 11 hours and 30 minutes. It is understood that the commissioners have numerous other tests to suggest before finally awarding the prize, even if they consider the Oshkosh machine to merit it.

PICKLING AND DEADENING.—It very often happens that jewelers want to give certain objects an appearance of gilding. The German *Watchmakers' Gazette* says that the following method will be found very useful; an appearance of brass will be given to the objects. These must be carefully cleaned of all fatty matters and dirt, or else the liquid will not act uniformly. Sulphuric or nitric acid is used, with or without tartar. The sulphuric acid is diluted with 10 to 20 parts of water. The sulphuric acid has the quality of dissolving the borax of the solder, which would otherwise have to be removed by mechanical means. As it has the property also of extracting the zinc from brass, and giving the objects a darker and redder color, it is not suitable where dipping only is required. As a general rule, therefore, nitric acid is to be preferred with about ten parts of water. The tartar has no influence on the color, and it is difficult to use it, as it must be applied with 30 parts of water in a boiling state. The dipped articles are then rinsed in water and dried in shavings unless pickling is required. For this the same acids are used, with the difference that sulphuric acid alone cannot be employed. Either nitric acid without any addition of sulphuric acid is used, which gives a bright surface verging on green, or nitric acid to which sulphuric acid has been added, which produces a yellow gold color. The acid bath has generally additions of table salt or snuff. The salt is decomposed by the acids, muriatic acid is precipitated and forms aquafortis with a part of the nitric acid. There is this advantage here, that most kinds of brass contain some tin, which is transformed into oxide of tin by the nitric acid, and as it is indissoluble in it it remains on the surface of the metal, while it dissolves in the acids of salt.

TWENTY THOUSAND SHOTS AN HOUR.—Dispatches from New York tell of a rifle battery lately invented in that city, which is so constructed as to deliver its fire either in a right line or in horizontal radiating lines. The barrels, ranging in number from six to twenty, are sufficiently apart to prevent heating from continuous firing, and are fired successively, instead of instantaneously, at the rate of 20,000 shots an hour.

DURABILITY OF LEAD ROOFS.—It is asserted, says the *American Architect*, that the lead roof of George Heriot's Hospital, at Edinburgh, Scotland, has lasted from 1650 to the present time, an occasional patch being the only repairing that climatic action made necessary.

A DEVICE FOR HOLDING CARS TO THE TRACK.—The *National Car Builder* describes what is called a "safety runner," which has been successfully tested on a railway in Minnesota. It consists of a bar of iron four and a quarter inches thick, suspended from the truck outside of and underneath the oil boxes, and secured across the ends of the truck by the brake-beams. It is braced between the wheels, and so constructed as to completely encircle and bind the truck. The runner hangs about four inches out from the wheels, on either side, and about half an inch above the trend of the wheel. It is claimed for this runner that it will hold the car to the track under any and all circumstances, and the trial certainly sustained the claim. The scene of the trial was in a sharp curve (six degrees). An outside rail, 30 feet in length, was removed, and the car, an empty flat, was sent over the gap at the rate of 15 miles an hour. The "runner" did its work beautifully; the truck dropped on to the ties, but was held close to the rail, and the car stopped in a distance of 30 feet. On the second trial the car was sent over the gap at the rate of 25 miles an hour, and ran about 150 feet, the "runner" holding it close to the rail, as before, and in each instance the car was replaced upon the track, uninjured, in less than 30 secouds.

FASTENING TIRES.—A German mechanic has invented a method of fastening tires which has, according to *Iron*, successfully stood the test of a series of experiments. A dovetailed groove is turned in the inner face of the tire, and a similar one in the outside of the skeleton, so that, when the tire is slipped on, the two come opposite to each other and form a channel of dowel-shaped section going all round the wheel. Into this channel is run some easily fusible metal (by preference pure zinc), which, on cooling, makes a firm connection between the tire and wheel. In carrying out the operation the tire is only slightly heated, and shrinkage of 1-1200 being found ample, and is then brought over the skeleton, which is laid in a horizontal position, and forced upon it. The zinc is then immediately run in through holes cast in the skeleton, if of cast metal, or drilled in other cases; thus the zinc is at once prevented from cooling while being run in, and is compressed, and thus rendered much stronger, by the subsequent contraction of the fire. That this mode of fastening, in addition to its simplicity and cheapness, offers full security, both against sideways shifting and in case of breakage of the tire, has been proved by experiments made in the central workshops at Frankfort.

LOCKING PLATE FOR NUTS.—A very simple locking plate for nuts has been invented by James Finney, of Braintree, England. A small pin is fixed a short distance beyond the nut. A circular plate, divided equally by 17 notches, fits easily over the nut in any of its six positions. The principle of the invention is the same as that of the vernier scale. As there are 17 notches in the plate it follows that three of them represent just one-seventeenth of one side of the hexagon nut; so that if the plate be moved round three notches, it will not fit unless the latter be moved round a distance equaling one-seventeenth of one side of the hexagon, or a distance which equals the one hundred and second part of a whole turn. The cost of the plate is small, as it can be made with sufficient accuracy of cast iron.

STEAM GENERATORS.—An English invention, for the purpose of saving fuel and regulating heat, introduces a marine steam generator, having a horizontal flue or flues, fired at each end, and provided with an uptake or uptakes at the center. He constructs the flues with a double hollow bridge at or near the center, so arranged that air can be admitted therethrough to mix with the products of combustion from one or other of the fires, by means of doors connected together, and operated by a lever or like appliance. The said air is heated in passing through the hollow double bridge, and serves to assist in the combustion of the gases generated at the end of the furnace last fed with fuel. The products of combustion pass away by the vertical central uptake.

GARMENT CUTTING MACHINERY.—The garment cutting machine which received the award at Philadelphia is being shown at the Paris Exposition. The following note is made on the construction of the machine. By adopting a long arm for carrying the upper pulley, a conveniently large table is obtained, and a certain amount of elasticity given to the knife, which is carried back, well out of the way, by the third pulley employed. Large and unwieldy pulleys are thus avoided. A simple and effective means of sharpening without removing the knife is provided in an emery-wheel fixed under the table, and driven from a pulley on the underneath shaft. We understand that from 3,000 to 5,000 garments can be cut weekly by one of these machines, thus rendering them invaluable to the large clothiers.

THE KEELY MOTOR.—William D. Marks Whitney, Professor of Dynamic Engineering, and George F. Barker, Professor of Physics in the University of Pennsylvania, publish a report in the Philadelphia *Ledger*. These gentlemen do not say that Keely is a fraud, but they evidently think so, and what they do say justifies the public in reaching the same conclusion.

SCIENTIFIC PROGRESS.

Fatal Fungus on the Salmon.

It appears that the salmon on this coast are found to be attacked by a fungus either identical or very like the one which has proved very fatal in England during the last year. At a meeting of the California Academy of Sciences recently, the subject was introduced by Mr. J. P. Moore, one of our ablest local mycologists. Specimens had been submitted to Mr. Moore by the Fish Commissioners. He said the disease, though recently noticed here, has long been known in Europe and fully described.

The disease is caused by a fungus, at least so classed at present, which first begins in the form of a delicate, web-like mass of semi-transparent, very fine threads, resembling a mold. It may begin either upon the head, gills, scales, or, as most commonly is the case in young fish, upon the umbilical cord. It seems especially to prefer the egg in its attack, and for reasons that will be shown. At its first appearance, an examination with the microscope shows this mass to be made up of simple threads. These in a few days, from eight to ten, increase in length and send out at times branches. These are club-shaped and are filled with protoplasm. Soon the protoplasm seems to break up and 200 zoospores are formed within the club-shaped tube. These you will observe under the microscope. At the base of these club-shaped filaments may often be seen shorter septate filaments, bearing on their summits a globular mass containing spores. These latter are what we call resting spores. Either zoospores, or resting spores may germinate; though the latter are undoubtedly intended to play the principal part, and serve to carry over the species from one season to another, as their name indicates—resting spores. The disease is known in treatises on the subject as *saprolegnia ferax*, though our species differ greatly from the one described under that name. It attacks not only salmon, but also trout, carp, gold fish, the eggs of fish, mollusks, batrachians, etc.

Whenever there are wounds, or whenever the circulation, from any cause, is weak, and the nutrition consequently slow, the attack is most likely to begin. For instance, the skin of fishes, placed in water not well aerated, in which the mucus is changed, becomes a fit point of attack. In such water, the bronchial respiration not being well accomplished, the gills may be the first point of attack. The secretions from wounds present very favorable conditions to the development of the disease. Eggs of fish or mollusks in such water, remaining quiet as they do, are most favorable soil for the disease.

Once developed, it can be readily transplanted from one animal to another in health, and there develop itself. This can be accounted for by the fact that it takes along with itself enough of its own substance to form a radius and serve as aliment, until the presence of the disease itself can cause an alteration in the normal mucus. It may readily be inferred from the nature of the fungus that warmth will tend to hasten it on to maturity. Warm, sluggish water, shallow pools, badly aerated reservoirs or tanks, containing, as they must, much nitrogenous substance, make a fitting breeding place for this disease. Death from this disease, no doubt, results from the prevention of proper respiration by covering the gills, as in the case of fish, rather than from any poisonous action of the plant. Experiments go to show that fish so attacked live but a short time, a few days at most. It might be inferred from what I have said that fish would be more subject to this disease at certain seasons of the year. This is, in fact, the case. Salmon at the end of the spawning season, especially, are subject to its attack, and great mortality prevails among them.

THEN AND NOW.—Prof. Du Bois Reymond is writing a notable series of articles for the *Popular Science Monthly*, concerning the uprising of the modern scientific idea. He takes occasion to contrast the present with the past as follows: "Man, whom we first met as a tool-making animal, is now become a rational animal who travels by steam, writes with lightning, and paints with the sunbeam. The re-conversion into work of the sunlight stored up in "black diamonds" multiplies his energy a million-fold. The Seven Wonders of antiquity, the engineering works of the Romans, bear no comparison with the enterprises every day undertaken by our own generation. The periphery of our planet threatens to become too narrow for man's genius. Hardly any secrets do its highs and its depths still conceal from him. Whithersoever man is powerless to go bodily, his mind penetrates with the aid of the magic key of calculation. In the blackest night, on the stormiest sea, his bark steers the shortest course; she dexterously shuns the track of the destroying typhoon. Geology does all that the divining rod was once supposed to do, giving us plentiful supply of water, salt, coal and petroleum."

PEPSINE FROM THE OSTRICH'S STOMACH.—According to the *Revue des Deux Mondes*, the ostrich hunters of South America, bearing in mind the almost incredible digestive powers of that bird, extract the pepsine from its stomach, and sell it for its weight in gold to dyspeptics.

MAGNETIC NICKEL.—A Russian physicist, M. Wild, sums up his researches on the magnetic properties of nickel as follows: Pure nickel can become permanently magnetic to a considerable degree, thus differing notably from pure (soft) iron. The maximum quantity of magnetism which pure nickel can retain, however, is only about one-half or one-third of that which hard steel can retain. The magnetism of nickel is less permanent than in steel after the magnetizing force has ceased to act; the gradual loss of magnetic force being greater with nickel than with steel. The temporary magnetism which pure nickel can retain is about double its permanent quantity, or about one-half of the temporary magnetism which hard steel and about one-fourth of that which soft iron can retain. These results verify, therefore, the general belief prevalent among physicists that in its magnetic properties nickel is notably inferior to both iron and steel.

COPPERY OYSTERS.—An observation recently made by M. Balland on copper in oysters is interesting. A number of so-called Portugal oysters, sent from Oran to Orleans in March, showed a remarkable green coloration. On being pressed against the palate they left a sensation of bitterness or tartness, and when placed in contact for some time with a well-cleaned plate of iron they deposited a thin red layer of metallic copper. M. Ballaud sought to determine the amount of copper by precipitation with an electric current; two oysters, without their shells, having been triturated and placed in a sulphuric acid solution; in 16 hours six milligrammes of copper were deposited, and several other experiments gave this amount of about three milligrammes for each oyster. Of the persons to whom these oysters were sent, some rejected them on account of their color; others took them and without any injurious consequences.

PHONOMOTER.—In order to exhibit the dynamic force of the voice, Prof. Edisou has constructed a phonomoter. The *Iron* says the machine has a diaphragm and mouth-piece similar to a phonograph. A spring which is secured to the bed-piece rests on a piece of rubber tubing placed against the diaphragm. This spring carries a pawl that acts on a ratchet or roughened wheel on the fly-wheel shaft. A sound made in the mouth-piece creates vibrations in the diaphragm which are sufficient to propel the fly-wheel with considerable velocity. It requires a surprising amount of pressure on the fly-wheel shaft to stop the machine while a continuous sound is made in the mouth-piece.

EXAMINATIONS FOR TRICHINA.—To detect trichina, suspected meat is often examined with a microscope. A Russian savant, M. Tikhomiroff, has suggested a new mode of isolating the muscular fiber. He divides the pork into small pieces and sets it to digest for about half an hour with an equal volume of chlorate of potash, to which is added four times as much nitric acid. The muscular tissue thus treated is put into a flask with distilled water, and agitated till it separates into its fibrillæ. These latter present, when the meat is infected with trichina, whitish fusiform swellings, observable with a lens, and in which the microscope reveals the presence of trichina.

WEEVIL ON LEAVES.—*Psyche*, the organ of the Cambridge Entomological Club, notes the recent introduction into the United States, of a weevil, which devours the foliage of many beautiful plants, and suggests to florists, who have been troubled by it, that it will be for their advantage to search at this time of the year, in the flower-pots, and in all waste soil about their hot-houses, for the larvæ and pupæ of these pests. The larvæ, which feed upon rootlets, are now pupating, and the destruction of every individual prevents the laying of a large number of eggs during the coming season.

MICROSCOPICAL JOURNAL.—We learn that a new scientific publication is to be undertaken in New York city, to be called *The American Quarterly Microscopical Journal*. It is to be a first-class publication, and will take rank with the famous English microscopical magazines. The editor will be Prof. Romyn Hitchcock, at 150 Nassau street, New York City. He is well fitted for the task and we wish him all success.

NATIVE FLOWERS AND FERNS.—The continuation of Prang's series of native flowers and ferns of the United States, illustrated with chromolithographs and text by Prof. Thomas Meehan, is worthy of the position accorded the work on the appearance of the first part. Five parts have thus far been issued, and the work is plainly shown to be unique and popular in design, and most praiseworthy in execution of both text and plates.

DIRECTOR OF PARIS UNIVERSITY.—The successor to M. Leverrier, as director of the Paris Observatory, has at last been appointed in the person of Capt. Mouchez. His functions are, however, purely administrative, the scientific direction being intrusted to M. Tisserand, an astronomer of great promise, formerly attached to the Toulouse Observatory.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

ZULEFF MINE.—*Ledger*, Aug. 17: Quite a stir is being made around this mine, which is located at Enterprise. From 15 to 20 men are employed, and an air of bustle and activity once more pervades this almost abandoned camp. Some nice looking rock is being got out, but the mill had not been started when the last accounts reached us.

VOLCANO ITEMS.—J. Griesback is below for the purpose of purchasing an engine for hoisting and pumping at his mine, the water supply at present being inadequate for such work. At Stewart's mill a partial clean-up of rock from Down's mine was made. The result justifies the high expectations. Thus far an average yield of more than $40 per ton is indicated, which is likely to be augmented when the gold is all taken from the batteries. At Downs' mine the ore improves in quality. Rock has been hoisted the last few days which the miners estimate at $100 to the bucketful. Though this estimate may be extravagant, there is no doubt that the quartz streak now being worked at this mine is very rich.

NEWTON COPPER MINE.—The work of taking out water has been pushed ahead for three weeks past, and is now nearly completed. Extensive repairs have been done to the car tracks under ground, and the mine is expected to resume ore extraction shortly, under circumstances as flattering as at any previous time.

CALAVERAS.

THORPE MINE.—*Citizen*, Aug. 17: This mine is looking well. The shaft is now down 85 feet, and they are still engaged in sinking. The lead is nine feet in width and pays well. The mill is kept constantly crushing.

GWIN MINE.—*Chronicle*, Aug. 17: Stopes are now opened on the 1550 level at the Gwin mine. The shaft and levels are being supplied with new seven-inch iron air pipe. The ledge shows very wide, but the ore is not high grade. The batteries are all in motion, and the yield of the mine is considerably above expenses.

EAST CALAVERAS.—At West Point a San Francisco company are rapidly developing the Granite mine. A San Francisco company has commenced operations on the Zacetero or Hall mine, at West Point. They have a new 10-stamp mill. At Mosquito the pumps in the Banner have been set at work. Everything is in readiness for active operations as soon as the shaft and stopes are freed from water. Levels are being run in the San Joaquin. At Sheep ranch the new machinery on the Wallace and Ferguson is in position, and it is expected to commence sinking the first of next week. Sinking is being vigorously prosecuted at the Chavanne mine. The Champion will soon have a mill of its own. At present ore from this mine is crushed at Carlton's mill.

INDIAN DISTRICT.

There appears to be two distinct mineral belts striking through the district in a north and south direction, the Tower mine being in the lower or eastern, and the Neal in the upper or western belt. The Neal mine has a 200 foot tunnel and 40 feet of shaft at points 300 feet apart. In the tunnel a crosscut shows a ledge thirty odd feet in width at a depth from the surface of 90 feet. This large vein is clean cut, seeming to be a perfect fissure, but varies in richness; the nine feet prospects well enough to mill at a good profit, and three and a half feet on the east wall, being quite flattering. The remainder or middle half, as it were, is of a rather low grade, but altogether the ore would reduce at a handsome profit if rightly handled. As yet it is of the free gold character, but it is not unlikely to turn more to silver, and possible in the end may partake of the character of the so-called "zinc-blend" or "black-jack," so conspicuous in the Tower mine, and which yields up in the hundreds of dollars per ton. The District has an abundance of fuel and timber for mining purposes, and a number of live springs capable of furnishing water sufficient and convenient for several mills.

LOS ANGELES.

SILVERADO AND ANAHEIM.—Dispatch to S. F. *Chronicle*, dated Anaheim, Aug. 16: Five tons of rich silver ore from Silverado, the new mining district in this county, reached here for shipment to San Francisco. Anaheim is the shipping point and base of supplies for Silverado, which is 25 miles distant. The district has already a population of 150, and there are a dozen developed mines. Trade has revived here wonderfully since the permanence of the mines is assured, and a market of considerable magnitude for our agricultural products will soon be opened.

GEOLOGICAL TESTIMONY.—Los Angeles *Express*, Aug. 10: "D. M. Adams says of the mines in Santiago canyon: It seems to me that there can be but little doubt as to the permanent worth of a silver-bearing lode, located in a hypozoic formation, having rich croppings and matrix of the most desirable character mineralogically, the ore from which smelts readily, the cheapest of all processes of reduction, and displaying infallible marks of perpetuity. I trust that our new mines at Santiago canyon do possess these elements, as stated by your correspondent, and there is every reason to accept the correctness of his account."

MONO.

VARIOUS MINES.—Bodie *Standard*, Aug. 14: Mr. J. H. Page has purchased a one-third interest in the Brooklyn mine. This claim is bounded on the north by the Bodie and on the south by the May Belle. A shaft was sunk one hundred feet, several months ago, and crosscuts run east and west and ledges were struck in both directions. Work was suspended on it, however.—The stir produced by the report that a strike had been made in the South Bulwer is hardly warranted by the facts, though a nice one-foot ledge has been opened, and from every indication it is getting wider as the work advances.—Work has been resumed on the Alice G. claim, owned by Dr. D. V. Goodson and Tom Madden. A shaft has already been sunk thirty feet.—The Addenda was purchased a few days since by W. F. Leon, Capt. M. C. McGleunon and Samuel L. Dixon. The shaft is down 135 feet and assays from the bottom vein over $40. Quite a large figure was paid, owing to the location and assays obtained. This mine is situated between the Bodie and Red Cloud.—Work still continues on the Paris, and samples of ore already taken out prospect very well. The drift has been advanced eight feet the past week; total, 70 feet. The shaft of the Last Chance was sunk eight feet deeper the past week, making a total depth of thirty-two feet.

NEVADA.

SCADDEN'S FLAT.—Grass Valley *Union*: This old mine, once dividend paying but afterwards drowned out, is to be revived by a new company. A sufficient amount of stock will be sold to raise a working capital of $10,000 to be used in erecting hoisting and pumping works. Work will be commenced as soon as possible, and it is expected to have the machinery in running order during the present summer.

LIVE OAK.—This mine has been sufficiently developed to show that it contains a true gold bearing ledge. Several cuts have been opened and four shafts sunk upon it, the deepest being 102 feet in depth. The ledge shows a uniform width of 20 inches which carries a good deal of free gold. Crushings have been made which average $23 per ton. The new incorporation, of which J. M. Keeler is president, and W. I. Tusten, treasurer, both of San Francisco, have contracted for a 10-stamp mill, on favorable terms. The mill is to be put up immediately, the machinery being sent from San Francisco, and it is expected that it will be ready for running within 40 days.

FALL CREEK.—Nevada City *Transcript*, Aug. 14: In the Diamond Creek mine, the south winze is on a good looking ledge that averages about four feet in width, while the north ledge shows a 3½ foot ledge that promises equally well. The rock in the main tunnel driving north is of extraordinary richness, and a new chute has lately been developed. The mill is kept in operation constantly, in order to crush the large amount of rock being taken out. F. A. S. Jones, owner of the Last Chance is driving a crosscut tunnel that will strike about 12 feet below the present depth of the 30-foot shaft. He has already taken out 15 or 16 tons of rock that looks well. A new bottom tunnel is being run in the Lindsey mine. Stringers have been met that may lead to a large ore body. A new mill is comtemplated. The old Cannon creek mill will probably be taken to the McCurdy. This mine has a regular chute, picked specimens from which have assayed as high as $200 per ton.

PLACER.

QUARTZ MINING ITEMS.—*Herald*, Aug. 17: Two Gould brothers, Jas. Ferguson and John Bryan, have cleared the old Booth mine of water and will soon commence systematic work. Shurtliff's Duncan hill tunnel is within about 15 feet of the main shaft. It will provide drainage and ore exit. T. M. Thoop, a persistent Duncan hill prospector, has at last found a streak that paid at first $20 and at last accounts $200 per ton. E. T. Loving works a ledge on Millertown Ravine, which has payed him very well from the start, and which at present is turning out some exceedingly rich rock. Indications are good. Bell's Bonanza, on Bald Hill, has left the pan and mortar and tried the St. Patrick mill. Forty tons yielded between $11,000 and $12,000.

FOREST HILL.—Systematic work is going on at several places on the Forest hill divide, the object of which is to get at the deep gravel deposits in the bottom of the old river bed, under the divide. The Excelsior company and Howell & Co., owners of the Jersey, Independent, Jenny Lind and other old claims, are among those that are pushing the development of this locality.

PLUMAS.

ITEMS.—*National*, Aug. 17: Encouraging reports come from the claim of Haun & Hickman, Clermont. They are again running the tunnel ahead, having completed their arrangements for a supply of good air, and are now progressing at the rate of from 20 to 30 feet a week. They have about 200 feet yet to run to reach the gravel. S. S. Taylor, on Silver creek, has a bank, about 14 feet deep, that prospects uniformly and well. R. Jacks, Enterprise claim, near Spanish ranch, has good prospects. Hungarian Hill has paid well this year. Better supply of water is wanted. Work is progressing satisfactorily on the new mill at Eureka. The Bunker hill claim, near Eureka, is said to be paying.

SAN BERNARDINO.

GOLD QUARTZ.—San Bernardino *Times*: It is believed that gold in paying quantities exists in a very large number of gulches in the San Bernardino Range, and would produce a very large amount of the precious metal if only water could be got to them, or the dry washer skillfully applied. Many men, by the application of judgment and proper mechanical skill, could make for themselves a business that would furnish them a good living in these gulches. But it is the quartz mines that are the most attractive at this time. Gold Mountain and Valencia Hill are each vast outputs of gold-bearing quartz that does not require to be mined but can be quarried for a lifetime to come. These quartz quarries will produce ore to give labor to thousands of men in the business of extracting precious metal therefrom, if only the business is conducted with proper mechanical skill and economy. These vast quartz mines are of a low grade, averaging in the neighborhood of $20 per ton.

SAN LUIS OBISPO.

OUR MINES.—*Tribune*, Aug. 17: Twelve or 14 years ago, several copper mines were opened and considerable labor and capital expended in mining apparatus, tunneling and prospecting; but owing to the undeveloped commerce, the irregularity of shipping, and the isolated and uncivilized state of the country, the enterprise was abandoned. Quicksilver mining has attained some importance in this county. Among the leading quicksilver mines are the Josephine, Oceanic, Ocean View, Pine Mountain. These are among the best quicksilver mines of the world, and their shipments of ore have, within the last five or six years, amounted to hundreds of thousands of dollars. These are situated mostly in the northern portion of the county, and are provided with first-class machinery and reducing apparatus. They have been effected by the low price of the metal, but still do some business. Placer gold diggings have been and are now being worked in the San Jose valley, some 30 miles east of San Luis Obispo, but not to any great extent, owing to a great scarcity of water. Enough has been done, however, to prove that splendid ledges of quartz exist in the hills above these placer washings. Lead ore is also found in the county. Chrome iron ore was discovered about two years ago, and a claim was worked by Mr. Wethered in the hills between San Luis Obispo and the coast. New claims have been discovered and the business is increasing. Harris & Co. own five mines near the headwaters of Chorro creek, some seven miles north of town. These mines are the Colorado, Soledad, La Rodilla, La Teresa and Los Amigos. Ten men are employed in the mines, and eight teams, hauling about two tons each, in the delivery of the ore. The Goldtree company own the La Trinidad, Salto and Devisadero. Feliz Bros. own a mine on Morro creek. The London Chrome company have delivered since July 1st, from their mines on a branch of Chorro creek, 34,400 pounds of ore, according to the *South Coast*.

SIERRA.

ITEMS.—*Mountain Messenger*, Aug. 17: The Oriental Quartz company, near Alleghany, are giving their quartz machinery a thorough overhauling. The Bald Mountain company are now employing about 86 men, have water to wash enough gravel to pay them. William Manson has the contract to sink the Pliocene shaft to bedrock at $50 per foot, he guaranteeing to sink 50 feet per month. The Savage company works near Milton, are down with the shaft about 130 feet. They have just got through a stratum of gravel and into pipe clay. The Schiveley furnace has again failed. There seems to be no hope of working Meadow lake ore. The Watt mine has commenced sinking its shaft, having drifted until it is thought they are over the channel. The indications are similar to the Derbec.

SISKIYOU.

SCOTT BAR.—Yreka *Union*, Aug. 10: This was the first place in Siskiyou county where gold was found, and is the oldest mining town in the county. Notwithstanding millions of dollars worth of gold have been taken from this vicinity there is plenty more left, though perhaps a little harder to get at. A great deal of mining is going on in the vicinity, the most of it requiring considerable expenditure of money before returns can be expected. On Quartz Hill opposite the town, Supervisor Garretson, E. Jacobs and John Marfield have an extensive claim and run a large hydraulic, and it is said profitably. Messrs. Jacobs, Reynolds, Tickner and Gilloon have a claim on the same hill which has just given them a good clean-up. Messrs. Maggoffy also have a claim on this hill. Also Messrs. Green & Holmes and Mr. Borland. The big flume of the San Jose Mill, Mining and Ditch company runs around the hill at the back of the town. They have just opened a claim below Scott Bar, but we did not learn how it was doing. Martin Andrews has also a good claim below the bar on which he has lately put a large hydraulic, or rather a "Little Giant," and the returns are said to be very satisfactory. Geo. Campbell has got his claim in the bed of the river below Scott Bar opened.

NEVADA.

WASHOE DISTRICT.

CON. VIRGINIA.—Gold Hill *News*, Aug. 21: Daily yield, 180 tons of ore, which is delivered at the mills as fast as extracted. The lower levels are still very hot and the progress of the prospecting drifts and advance of the ore stopes necessarily slow. The 2,050 station in the C. & C. shaft is being opened ready for future use. There yet remains about 150 feet of the shaft to repair, 100 feet of which will require considerable enlarging, but it is hoped that after the 1,400 station and drifts connecting are reopened, a sufficient circulation of air will be secured to permit of better progress. Repairing the connecting air gallery with the Gould & Curry on the 1,550 level is going steadily forward. Retimbering the main south drift on the 1,300 level is making the best of progress.

CALIFORNIA.—Daily yield, 200 tons of ore. The opening up of the sill floor going north from crosscut No. 4 on the 1,650 level is making good progress, the face still in good ore. The north ore stopes on the 1,750 level are also yielding good ore, and look well as they are advanced to the northward. The main north drift from the Consolidated shaft on the 1,650 level is being steadily advanced, the face in softer ground. It is believed that this drift will cut into the north ore body in a day or two more.

OPHIR.—The repairs to the main shaft above the 1465 level are making good headway. Retimbering a portion of the drifts on the 1300 level has been commenced, in order to keep open the air connections in the upper portion of the mine. Sinking the joint California winze below the 1900 level on the south line is going steadily forward, the bottom in hard blasting porphyry. It is now down 93 feet. Sinking No. 1 winze below the 2000 level is making good progress, having passed downward until through the ore into the west wall of the vein. The ore is now gradually passing out of the shaft to the eastward, the underside of the vein having assumed the regular easterly dip of the Comstock.

YELLOW JACKET.—On the 2400 level the south drift is now in 177 feet from the winze. The face still continues in birds'-eye porphyry with occasional streaks of quartz. No water. The new shaft is down 1,697 feet; bottom in dry, good working ground.

LEVIATHAN.—The lateral drifts both north and south on the 750 level are still running in the regular black dyke formation immediately underlying the ore vein. The north drift shows especially well this week.

JULIA CON.—The water is drained from the 2000 level and good progress is being made in cleaning out the main south drift and crosscut No. 1 on that level. Crosscut No. 2 has not yet been reached. The level is intensely hot, and but slow progress can be made with the work until it is cooled off.

CROWN POINT.—The north drift on the 2300 level is being pushed forward with the usual vigor to reach the north line of the mine. It is now in 275 feet from the winze, and has something near 200 feet yet to run to reach the Kentuck line.

CON. IMPERIAL.—Crosscut No. 3 south, near the center of the Imperial ground, is in a very encouraging body of quartz, giving good assays.

SUCCOR.—The new air compressor is completed ready for use. Sinking the shaft has been resumed and is making good progress, the bottom in good blasting rock.

SUTRO TUNNEL.—Face of header still in quartz and porphyry with streaks and bunches of low-grade ore. Total length of tunnel at the present time, 20,385 feet.

LADY BRYAN.—Good progress is being made in freeing the mine from water, the new machinery working finely.

SIERRA NEVADA.—Sinking the main south incline has made good progress during the week past, the bottom of the winze cutting occasional bunches of quartz, some of which continue to give good assays. To all appearances the shaft is passing over the top of a body of ore, the width, depth and extent of which it is an impossibility to yet determine. Sinking the winze was suspended last evening for the purpose of putting in new reels and other machinery at the head of the shaft, which will take at least two days' time. The discovery of the new ore body has infused new life into the mine, and the managers are going to work to develop their mine with a will and energy that betokens the greatest faith and the best results. The working force of the mine has been increased to over 175 men, and the present rate of expense will be $1,000, or more per day.

SILVER HILL.—Sinking the main incline is making good progress, the bottom in good blasting ground and the water giving but little trouble. The main north drift on the 900 level is making steady progress, the face in very favorable vein matter. The east crosscut from this drift is passing through a fine vein formation, carrying considerable quantities of good quartz and some ore, having the appearance of being only the outskirts of a fine mineral-bearing vein.

UNION CON.—Cutting out and opening the chamber for the joint Mexican winze on the south boundary line on the 1600 level is making good progress, and will be completed ready to commence sinking in a day or two more. This winze will occupy a very important position, will enable the prospecting and opening up of a large portion of entirely virgin ground, and will greatly aid the ventilation of both the Mexican and Union Con. mines.

HALE & NORCROSS.—The pumps working in connection with those of the Savage, lowered the water to within a few feet of the 2100 level, when a disarrangement of one or two of the small pumps in the Savage threw the greater portion of the work on the Hale & Norcross, and permitted the water to rise several feet in the shaft. Everything is again in good running

order, however, and the water is being gradually lowered.

BELCHER.—A serious break of the pump-rod occurred at the main north incline last night. It will probably take a week to repair the damages, but will have a no more serious effect than to delay the crosscutting of the 2,360 level for that length of time, as it would hardly be advisable to commence it with only the small donkey pumps to keep down the water in case a strong flow shall be struck.

BULLION.—The west crosscut on the 2,000 level is steadily advancing, the ground in the face being softer and carrying streaks of quartz and slips with a slight moisture, indicating a near approach of water. The east drift on the 1,840 level has not yet been started up, on account of there being no decrease in the flow of water. The east crosscut on the 1,700 level is steadily advancing, the face in porphyry carrying streaks of quartz. Sinking the main incline has been delayed for the past three days on account of having to put in a tank to catch up the water. This is now completed and the sinking resumed.

CON. DORADO.—During the past week the shaft has passed through a fine vein of quartz from five to seven feet in width, dipping to the eastward. The quartz is of very favorable character and gives low assays. Very good progress is being made in sinking, and the fine stringers of quartz being met with of late give the best possible encouragement of soon finding something better.

JUSTICE.—The double winze below the 1300 level is still in quartz and ore. The upraise from this level is also in good quartz showing spots of ore. The winze from the 1225 level to connect with the upraise is in fine quartz. The south drift on the 1150 level running toward the Silver Hill is showing some fine streaks of excellent ore.

TROJAN.—The ore extracted still continues of a good quality, the car samples showing an average of $38 per ton. The bullion receipts up to the present date of the month is nearly $9,000. The south drift from the fourth station is advancing at a very rapid rate of progress, the face in a splendid solid body of quartz, yielding assays ranging from $5 to $20 per ton.

SAVAGE.—Yesterday morning the water had been reduced to the top of the station at the 2100 level, when some trouble occurred with the small donkey pumps, permitting it to rise rapidly in the shaft. The necessary repairs have, however, been made, and the pumps are again getting the best of it.

UTAH.—The northeast drift on the 1150 level is being steadily advanced, the face in porphyry of a softer character. The upraise from the 1150 station of the incline to connect with the main perpendicular shaft is nearly completed. The 1150 station of the incline is finished, and putting in the new hoisting machinery has been commenced. Sinking the main incline below that point is making good progress. It is now down 85 feet.

CHOLLAR-COMBINATION SHAFT.—New foundations for a new set of boilers are being put on the surface. The excavations for the pumps in the main shaft below the 1600 level are rapidly approaching completion. The north drift on the 1600 level now being run to connect with the Sutro tunnel for a drain is advancing at the rate of five feet per day, the face in hard blasting rock.

NORTH CON. VIRGINIA.—The mine is entirely drained and sinking the main shaft is making the best of progress, considering the extreme hardness of the rock encountered.

CALEDONIA.—The north drift on the 1600 level is steadily advancing, the face in hard blasting ground. The east drift on the 1600 level is also being pushed vigorously ahead in hard blasting rock. The south drift on the 1400 level continues in quartz and favorable vein matter. It is the intention to close the mine on Saturday next for 24 hours, in order to make some necessary repairs to the machinery.

GOULD & CURRY.—The south drift on the 1900 level has been cleaned out and repaired to the joint Savage incline on the south line, which greatly assists the circulation of air in that portion of the mine.

BEST & BELCHER.—The joint east crosscut from the bottom of the winze on the 1900 level is being steadily advanced, the face in soft porphyry.

NEW YORK.—The north drift on the 1100 level is making rapid progress, the face in very favorable vein matter. The south drift is showing some quartz of a very encouraging description. Everything working finely.

ALTA.—A large portion of the vein on the 1250 and 1350 levels is already stripped, ready for crosscutting whenever it is desirable to do so.

BULLION DISTRICT.

YOUNG AMERICA.—The Young America mine, about five miles south of the Osceola, originally owned by Phil Depanger, who discovered it in '71, has been sold to a company of capitalists, who have 10 or 12 men engaged in extracting ore, with an Iowa man, by the name of J. N. Hill, as Superintendent. Some 800 or 900 tons of ore have been taken out and worked, some in Salt Lake, some in California and at other points on the coast, and it yields between $300 and $400 in silver to the ton.

CAMPBELL DISTRICT.

OSCEOLA.—Eureka *Sentinel*, Aug. 15: The Osceola mine, located in the Campbell district, about 22 miles south of Beowawa, and 15 miles northwest of Cortez district, promises to number among the richest mines of the State. It was discovered about three months ago by Mr. Depanger, and is now owned by a company, composed of himself, C. M. Twiss, and Jim Campbell, the original discoverer of the district. Several assays have been made of ore taken from this mine, giving an average assay of upwards of $600 to the ton. By testing the ore taken from different parts of the mine, it has been found that it all runs about the same. The rock contains very little metal other than silver. There are but very few men in the district at present, though prospectors are now making in that direction, attracted by this rich find. This company will set several men at work immediately, developing the mine and a few prospecting. A boarding house for the accommodation of the miners is being erected, and all necessary steps taken for operating the claim. Several car-loads of ore is now at the railroad, awaiting shipment to Salt Lake. The mine is situated on the summit of the highest mountain in the district, though easily accessible by teams.

RUBY MOUNTAIN DISTRICT.

RUBY district has lately been organized out of a portion of the Bald Mountain district, and a section of country stretching along the range to the northward in the direction of the overland road, a little east of Jacob's wells. It lies in White Pine county, and is perhaps 45 miles from Eureka in a northeasterly direction. Many valuable ledges are reported, and wood and water are abundant. There are several miners at work, with flattering prospects in the district. The most promising thing, however, is a mammoth copper vein owned by Mr. Olmsted and his associates. We have been shown some very excellent specimens of oxide of copper, estimated to carry at least 50% of pure metal. In view of the fact that the ore may be cheaply reduced on the ground, this is considered a paying proposition. The vein is believed to be an immense fissure, and can readily be traced for a distance of nearly two miles. It runs in a northerly and southerly course. The country rock is granite on one side and slate on the other. The new district is within 12 miles of the Cold creek settlement on the old Hamilton and Elko stage road.

NEVADA ITEMS.—It is rumored that a quartz ledge at least 15 feet wide, cropping out over a mile and averaging over $600 per ton, has been found in Peavine District. Rumored rich strike in the Jefferson mine. The Hillside will probably not start before September 1st. Some Revenue mine ruby ore assayed $25,719.14 per ton; $21,653.22 silver. The Phœnix new hoisting works is on the ground. Eagle mine, Lewis District, erecting hoisting works, and putting in pumps.

COLORADO.

SAN JUAN ITEMS—*Prospector*, Aug. 10: The San Juan and St. Louis Smelting Company started up on the Ang. 4th. The mines in the vicinity of Rose's Cabin continue to improve. A large amount of ore from this vicinity will be shipped to Lake City this season for treatment. The Sunnyside district is looking up once more. New men are expected to take hold of some leads there. The Red Rodgers lode, Pokeepsie Gulch, made its first shipment of ore for the season, recently. It was shipped to the Gladstone works of Dow & Waters, and assays gave over 600 ounces to the ton. The San Juan lode, in which Joe Cuenin and Roucbe are largely interested, gives assays as high as 593 ounces. A rich body of sylvanite, running nearly 300 ounces silver and considerable gold, was struck in the Mastodon a few days ago. F. F. Riggs' Bobtail mine in the summit district is improving. Twenty-six sacks of Montezuma ore, packed all the way from Yellow Mountain to Silverton, netted $54. The Pandora, owned by Lawthian and Medley, has exposed an ore body varying in thickness from 16 to 20 feet and assaying from $20 to $150 in gold and from $10 to $80 in silver. The placer claims on the San Miguel have been sold. In from 40 to 60 days, it is hoped, hydraulicking will commence.

GENERAL ITEMS.—Three men took out in three days, ore from the Ogallallah, which sold for $73 cash—188 ozs. of silver, a trace of gold per ton. The Melvina mine has resumed work after a suspension of a week on account of foul air. Air pipes have been put in. The Triune mine at Salina is still producing fair quantities of rich ore. The Atchison mine at Salina is again undergoing a transformation. A reverberatory furnace is being put in preparatory to trying chlorination. The Ohio company which has bought the western portion of the Montana mine at Salina, are having the shaft sunk twenty-five feet by contract, and expect to push the development of the mine rapidly. The Fannie lode, just west of Sunshine, is a promising prospect owned by R. C. Broadwell and Wm. Sellers. The mill returns run $200 to $250 per ton. Deitz & Higgins expect to be shipping coal from their bank near White Rock before cold weather sets in. C. C. Alvord reports to the Ouray *Sentinal* ore from the Virginius mine, in Mt. Sneffels district, that ran 530 ounces to the ton. The Summit mining district—the only gold mining district in the San Juan county—is sending out encouraging reports. The Little Annie mine is doing particularly well. The workmen in the tunnel through Raton mountain are reported to have struck a vein of excellent coal. Delphi, located in Sugar Loaf mining district, is in a prosperous condition. The mines that are being worked are doing well. The Little Daisy is attracting much attention, and the prospects are that it will prove to be one of the best mines in the county.

News in Brief.

THE strike of Paris cabmen is virtually at an end.

THE Indian famine continues very distressing.

A REVOLUTION has broken out in San Domingo.

AUGUST 16th Parliament was prorogued until November 2d.

A THOROUGH survey of the Columbia river bar is in progress.

THE wool crop of Douglas, Oregon, this year is put at 1,500,000 pounds.

HOP lice are troubling the vines in central New York to a fearful extent.

AMERICAN dried apples are now in demand in most of the countries of Europe.

IN three days 130,000 quarts of blackberries were shipped from Vineland, N. J.

AUGUST 13th, a fight occured in Ottawa between Young Britons and Union men.

THE run of salmon in Fraser river stopped when the eclipse took place.

IN Lane county, Oregon, the wheat is found to be of better quality than for several years.

AN English miser has left all his money, over $300,000, to charitable institutions.

THE British ship *Lupata* carries 35,580 cases of salmon from Oregon to Liverpool.

IT is rumored that the Western powers have agreed to a French protectorate over Tunis.

GEN. WILLIAMS is preparing to reclaim 7,000 acres more on Union Island this season.

TURKEY has no money with which to carry out her reforms. Now England step forward.

FIVE masked men boarded a Kansas Pacific passenger train Aug. 13th, and carried off $5,000.

THE lands north and west of Fresno will probably soon be watered by canals from the San Joaquin.

THE Solano winter sown grain is turning out much better than the summer-fallow or volunteer.

THE crops in the Dominion of Canada are excellent. The yield of grain is greater than ever before.

BAKER PASHA and three colonels are now the only English officers retained in the Turkish service.

ONE Palmyra, Wis., man has shipped 75 tons of cheese so far this season. Much of it went direct to England.

THE British fleet at Constantinople organized an international regatta. The first sailing prize was won by an American yacht.

THE Mexican minister at Washington says that it is the wish of Diaz to keep peace with the United States.

THE whole number of incorporations filed in San Francisco last year was 409, of which 265 were by mining companies.

THE Alcalde of Newtown, Mexico, has given information implicating high Mexican authorities in border troubles.

THE last shipment but one of nuggets from the Silver King mine, in Arizona, assayed in Frisco $17,000 per ton.

A BOY died recently in London from the effects of a blow on the head with a book inflicted by his teacher in school.

THE Madras Presidency in India has been suffering from a plague of locusts, which has greatly aggravated the distress from famine.

Rev. George Gilfillan, author of "A Gallery of Literary Portraits," "The Bards of the Bible" and "The Scottish Covenanters," is dead.

JOHN BOGGS, of Colusa county, says that a million dollars worth of grain has been destroyed in that county this season by rust.

COMMISSIONS for the reorganization of Bulgaria and Eastern Roumelia will meet in September.

THE net yield of the Eureka mines for the quarter ending June 30th was $788,988.74, upon which a tax of $15,799.77 was levied.

A NINE days' prayer has been ordered in all the Catholic churches of New Orleans for the abatement of the yellow fever scourge.

THE Servian Minister of Finance is negotiating with Paris bankers for a loan of 24,000,000 francs, to redeem debts contracted during the war.

WASHINGTON August returns to the Department of Agriculture show an average condition of the cotton crop in 10 cotton States of 95, a decline of 4.

ALL the banks of Chili have suspended specie payments. The Government has drained them to carry on an intended war with the Argentine Republic.

EINSTEIN BROS., San Francisco, wholesale boot and shoe manufacturers, closed their doors August 16th. Liabilities, $800,000. Over 200 employee were thrown out of work.

AT the Geneva World's Convention of Young Men's Christian Associations there are delegates from America, Belgium, England, France, Holland, Spain, and Protestant cantons of Switzerland.

THE four per cent. loan is a success. The total amount subscribed will, at the end of August, be about $65,000,000. An encouraging feature is that many small subscriptions have been made.

IT has transpired that the murder of Tullis on his ranch beside the Sacramento river August 1st, was accomplished by assassins hired to do the deed by Troy Dye, public administrator of Sacramento county. Dye's object was to make money from Tullis' estate, which would come into his hands as public administrator. Dye and one of the murderers named Anderson are in custody and have made full confessions. One of the murderers is still at large.

HON. BAILIE PEYTON died August 18th.

POSTMASTER-GENERAL KEYS is coming to California.

THE natives of New Caledonia are playing the part of our Indians.

A DANISH colony for Washington Territory is being planned.

TRADE in the Samoan Islands is reported dull. We need not go so far to get such news.

THE official estimate of the number of deaths from famine in India is 1,850,000.

FOUR years ago the Tasmanian export of tin was $35,000, while last year it was $1,500,000.

HUMBOLDT river, Nevada, is to receive 2,500 catfish, and the Truckee river, 500,000 salmon.

THE universal postal treaty, recently concluded at Paris, has been approved by the Washington Cabinet.

A COMMITTEE has been appointed in San Francisco to collect subscriptions for the yellow fever sufferers.

THE Oldham, England, weavers accept the five per cent. reduction of wages demanded by the employers.

SIXTY per cent of the yellow fever deaths is of unacclimated people and 75% of the remainder of children.

THE Porte, to prevent farther depreciation of the Turkish currency, has decided to raise import duties on salt, tobacco and spirits.

OWING to the failure of the Coen River gold field in Queensland, many diggers are now turning their attention to New Guinea.

THE Hungarian government has forbidden the export of arms and munitions into Servia and Montenegro.

A THEATRE has been opened in Pompeii, where the first performance will be given since the eruption of Vesuvius, in A. D. 79.

SEVENTY-FIVE acres of vineyard at Malaga have been attacked by the phylloxera, the ravages of which are increasing alarmingly.

THE Mexican Minister of the Interior has ordered the purchase of 50,000 eucalyptus trees to be planted in and about the City of Mexico.

FIFTEEN HUNDRED pounds of tobacco have been found secreted under a floor of the Issue House at Crow Creek Agency. Lo, the poor Indian!

DR. SCHLIEMANN is at Constantinople, and intends resuming his excavations in the Troad if he can obtain from the Porte 50 soldiers as a guard against robbers.

THE McCloud River Fish Commissioners will get 2,500,000 young salmon this year to replenish the stock in the Pitt, McCloud and Sacramento.

HON. ALEXANDER DELMAR has presented the University of California library with his private collection of 2,000 works on political economy and kindred topics.

A VOTE was taken in Cincinnati, August 14, on the question of issuing $2,000,000 bonds for completing the Cincinnati Southern Railroad. Majority in favor.

M. V. SPARKS of Dry creek, near Wheatland, Yuba county, recently threshed 14,300 bushels of wheat, the yield of 500 acres, an average of 28½ bushels per acre.

THE 40-stamp quartz mill of the Gold Mountain mining company in Bear valley, 35 miles from this place, was destroyed by fire August 14th. The mill cost $80,000.

AMONG the successful American exhibitors in the Paris Exhibition are the McCormick reapers and Pullman's palace car. Specimens of American coal and wheat received gold medals.

AN 18-year old boy of Nevada City has ruined himself by opium smoking. He has tried to abandon the habit, but says he cannot. He is a mental and physical wreck.

BISMARCK has instructed the German attache at Constantinople to inform the Porte that a continuance of its ambiguous policy would risk the existence of Turkey in Europe.

THE Mono County Bank will soon be in running order. Howard Hastings, formerly manager of the Merchants' Exchange Bank, of San Francisco, is cashier.

EDWIN RUSSELL, formerly of the Bank of British Columbia, has organized a syndicate of English capitalists for the purpose of taking machinery to Cariboo to reduce the ores of that mineral region.

A COMPANY of five men are busily engaged in taking out and shipping gold and copper ores from well-defined ledges situated on King's river, Inyo county, some 30 miles across the Summit from Independence.

TWO HUNDRED catfish have been sent this year to Yuba county, 500 to San Joaquin, 1,000 each to Butte, Sonoma, Ventura, Clear lake, and the Colorado river. No further distribution will be made.

A CABINET officer is authority for the statement that nothing has occurred lately to change the relations between Mexico and the United States, and that peaceful means will be employed to settle difficulties.

PATRICK MAGUIRE, wandering in the tunnel of the South Utah works on the Comstock, fell to the bottom of a winze. He bruised his head, broke his left thigh three times and his right twice. It was 70 hours before he was rescued.

LARGE quantities of corundum are being mined in Alabama. Sixty-five dollars per ton is paid for it on the ground. If the main vein is struck, the only mill in the United States will be removed from Massachusetts to Alabama.

AUCKLAND gold fields have not brilliant prospects, but settlement is greater, more machinery is being introduced, fencing proceeds, cattle and sheep multiply, and fields of grain take the place of uncultivated lands. This is better than gold.

Continued from page 114.

raises the charge. This system applied to a shaft of 650 meters in depth (2,132 feet) offers the advantage over the hoisting with cables of heing independent of the depth. But it is necessary that it should he tried some time hefore pronounciug upon its value.

The hoisting machinery taken altogether shows the advances that have been made, dictated by the concentration of the production to a few ehafts, from which have often heen extracted from a depth of more than 500 meters (1,640 feet) 600 to 800 tons in 10 hours.

The flat cables are often of steel; their strauds have heen increased to give a great suppleness with the strength necessary for the charges to he raised. The cages have several stages to receive several cars, and are often of steel to reduce the suspended weight. The appliances for safety, parachutes, corrugated wheels, signals, etc., have heen multiplied and simplified to make their working certain in spite of the rapid working in vogue in the shafts at present.

The guides have heen attended to with increasing care, and rigid ones of wood or of iron replacing those of round rope, particularly where the hoisting of workmen in the cage necessitates an efficacious parachute. The raising and lowering of workmen in the hoisting cage is in all cases the rule in mines deeper than 300 to 400 meters (984 to 1,312 feet), the special apparatus, oscillating timhers or columns *(tiges osciblantes)* not being necessary, the maximnm depth of shafts in France not heing at present greater than 650 meters (2,132 feet).

In the large permanent pumping machinery it has heen attempted to augment the power of the apparatus hy increasing the numher of strokes of the piston per minute. Tbis increase is obtained hy working the pumps with eompound engines, or, better still, hy rotating engines with a continuous motion and a fly wheel. On the other hand it has heen aimed to simplify thc apparatus of the pumps and to augment the free space in the shaft hy adopting a single pump rod of a working length of 200 meters (650 feet), or, better still, hy installing at the hottom a rotating pump, which forces the water directly to the surface by a column of pipe occupying only an insignificent space in the ehaft. In all the machiues of great power, the condensation and the expansions are pushed as far as possihle.

Considerahle progress has heen made in ventilating the works; the mechanical apparatus of ventilation, centrifugal ventilatore as well as those of Lemville are widely used, and of late have been made often of eonsiderahle dimensions to send an augmented volume of air through a careful system of conduits to every part of the mine.

Numerous improvements have been made in the lighting of mines. The mineral oils are generally employed for the fixed lamps, and the mode of enclosing safety lamps has heen improved, and, at the same time, the degree of safety given hy them has heen increased hy some modifications of detail.

The electric light has remained the great exception, even in the works where the screening and sorting is done, except in the open air, where it seems likely to render some service.

The apparatus for safety have heen increased, owing to the simnlifications added to the primitive arrangements exhihited in 1867. The signale have heen usually limited to the ancient hammer worked hy a metallic cam, in spite of the happy efforts made in eome minee to replace it hy electricity.

The apparatus for separating and concentrating the ore extracted have made great progress, ahove all from the point of view of cost occasioned by the apparatus, of the reduction of the mannal lahor necessary, and of the less amount of slack occasioned hy screeniug. In this connection might be mentioned the ecreening hy concussion of Commentry, and the endlese wehs or cloth sheets *(toiles sans fin)* of the mines of Lens.

In the washing of coal the power of tbe apparatus has heen increased without reducing its effectiveness. In the washing of mineral ores the general use of the screens continued to small sizes, and the filtering screens of the Hartz mountains have transformed the mechanical preparation in giving it a rapidity unknown hefore, and in reducing the loss hy washing it has also pushed still further the washing of fine matter.

The industry of the agglomeration of coal (*agglomeres de honille*) is a uotahle development of Frauce since 1867, and the use of dry pitch as a cement is almost entirely substituted for liquid pitch, it giving a more solid mass, and hurning with less odor and smoke.

Great perfectiou has heen reached in the apparatus for the agglomeration, especially for the grinding, for which entirely new designs have been invented.

In the carhonization of coal the augmentation of value of the fiue coal has led to the adoption of coke ovens hetter adapted to large production, and consequently to the ahandoning nearly alwaye of thoee admitting air directly, and substituting for the ovene (*fours a carneaux*), and eometimee even ovene completely cloeed, permitting the collection of the products of distillation, the ammoniacal liquor and the tar.

The relative purity of fat coals hae led to the carbonization of eemi-hituminoue coals, or to the mixing with the fat coale a considerahle amount of lean coal; this reeult cannot he attained except hy grinding them more finely and mixing them most intimately, and also hy decreasing greatly the size of the ovens, so as to largely increase the heated surface in order to promote more perfect carbonization. In short, the constant augmentation of the dimensions of shaft furnaces, which prevents the use of any hut the most solid coke, has increased very much the higbt of thc coke oven, leading to the use of those which are straight and high, prolonging often the duration of the carbonizing.

The Engineer.

The State Survey on the Rivers.

The Stockton *Independent* says: Wm. Hammond Hall, State Engineer, and Edward Yorke, one of his assistants, were in the city on Saturday, and left yesterday morning by their steam launch. They have heen on a tour of inspection of the various tide gauges, stationed at different points on the two rivers, and looking after the parties in the field. Both the parties out are making good progress, the topographical party, under Mr. Klugel, having ahout completed the survey from the mouth of the Stanislaus down Old and Middle rivers, and are now camped a ehort distance from Stockton, while the hydrographic party, under Mr. Boschke, are working down the Sacramento river, and are expected to reach Sacramento in ahout a month. After completing the meander of the San Joaquin river Mr. Klugel will go up the Sacramento, connecting his survey with Mr. Boschke's work, while the latter will come up the San Joaquin, counecting with the lines established hy Mr. Klugel. The hydrographic work is heing doue very carefully, and soundings are taken the whole length of the river. The plan is to select stretches of the river of ahout a mile at frequent intervals, where a cross section characteristic of the stream may he found. A hase line is then established on the bank, and a true meridian found from observations on the stars. From the hase line, at intervals of 200 feet, lines are run across the river at right angles to the stream, and soundings carefully taken on these lines every 20 feet. From these soundings a section of 600 or 700 feet is eelected where the stream is most nearly uniform, and at each of the sounding stations the electric current meters are lowered, and the velocity of the curreut measured at each five feet in depth. An average section will thus give a hasis for calculation of the actual discharge of thc river. At high water this operation will be repeated, and data ohtained which will enahle the engineere to calculate the amount of water which the river will carry at e ch point and at every stage of hight, and thue to find out its defects aud determine the hest means to remedy them.

Fast Time on Railways.—An Eastern railroad paper says that probably the fastest time ever made hy regular trains in this country is now made hetweeu New York aud Philadelphia. The new line made up hy the Ceutral of New Jersey, Delaware & Bound Brook and North Pennsylvania, ruus one train between tbe two cities in two hours and five minutes, includiug the ferry crossing of the Hudson river. The running time for the 88 miles from Philadelphia to Jersey City is one hour and 56 minutes, the train stopping at Trenton Junctiou and Bound Brook, and also for the grade crossing at Elizaheth. The corresponding train from New York makes the run in two hours and five minutes, with the same stops. The Pennsylvania runs its fast train from West Philadelphia to Jersey City, 89 miles, in one hour and 54 minutes, the return train making the trip from Jersey City to West Philadelphia iu one hour and 50 minutes. These trains stop at Treuton and for the grade crossing at Elizaheth, and are also ohliged to reduce speed over the Trenton hridge, and for nearly two miles passing through the city of Newark. Special trains have made as fast or faster runs, hut we do not think that an average speed of 48 miles an hour has ever hefore heen required hy regular time-tahles in this country.

Roman Roads in Palestine.—A recent traveler in Palestine was astonished by the uumher and preservation of roads huilt in the Roman era. They were laid out on all the main routes and were constructed so perfectly that in many sections they endure to-day as well as if finished not long ago. The country of Palestine was one of the moet difficult sort to carry a system of roadways over, and yet its ohstaclee were surmounted with the least possihle expenditure of lahor. Every route was curhed on eacb side hy lines of stones projecting from one to two feet ahove the surface of the soil; hetween these houndaries the avenue was paved; streams were crossed hy bridges, whose style remains preserved alone in those of Italy to the present hour—as, for exainple, those of Venice; valleys were traversed hy viaducts; and the causeway carried the line up or down mountain sides, either hy piers of masonry or in channels sufficiently wide, cut out of living rock. Often zigzage and etepe were resorted to in climbing steep ascents. Whenever the street passed over eolid rock, the wear of chariot wheele in the course of time made ruts, which remain today ae plain and deep as when the laet car passed over.

The Suez Canal.—The business of the Suez canal appears to have been euccessful during the past year. According to the report submitted to the shareholders' meeting, held in Paris, June 11th, the expenditures for the year euding December 31et, 1877, amounted to $5,847,742, distrihuted as follows: Interest, $2,331,093; admiuistrative expenses, $227,200; charges of the domain, $95,405; transit and navigation service, $323,979; repairs, $456,667; interest on coupons, $340,000; interest on sbare capital, $1,993,450, and some smaller items. The revenue amounted to $6,795,129, of which the receipts from navigation were $6,590,501. The surplus was $947,585, from which, deducting the statutory reserve, $47,369, there remains $900,216 as net profits.

Texas and Pacific Extension.—An understanding bas heen effected which will extend the Texas and Pacific railroad from Fort Worth to Weatherford, Texas. The construction company is to grade and tie the 31 miles, and the Texas and Pacific company will put down the iron. The cost of construction is estimated at $140,000, for which the road is to issue its ohligations, payahle in three years, or first mortgage honds to he issued next March. The construction company will at once advertise for hids, and the road is to he in operation for the fall trade.

An East Indian Bridge.—Detailed particulare have been received of the ceremony of opening the Empress bridge over the Sutlej, in India. It is described as a maguificent piece of engineering, consisting of 16 spans, each 250 feet long, and is the completion of one of the principal links of a vast chain of railway communicatiou now in course of progress. The cost of erection has been ahout 59 lacs of rupees.

Appointments of the New St. Petersburg Observatory.—The new magnetic observatory at Pavlovsk, to serve as an annexe to the Central Physical Observatory of St. Petershurg, has been opeued. The new observatory covere ahout eight hectares of surface, and the situation is in all respects favorable for the delicate work for which it is intended. The establishment comprisee three principal scientific huildings, the principal building of stone and surrounded by a terrace for meteorological observations; a double arched structure in stone covered with earth for observations in maguetic variation; and a woodeu pavilion, without a particle of iron, for absolute magnetic measurements and for dcterminations of time. The Pavlovsk Observatory is furnished with the most improved and most recent scientific instruments, and like the Central Physical Observatory of St. Petersburg, is a model establishment of its kind. As we have said, the pavilion for absolute magnetic measurements is without a particle of iron; all the metallic parts, locks and padlocks, keys, doors and chimneye of stoves, etc., are of copper or hrass, and each of these objects has heen tested by a particularly sensihle magnetometer. The same test has heen applied to the limestones of thc fouudation, the hricks of the stoves aud the chimneys, the grauite supports of the instruments, etc. In sbort, every precaution has been taken, hoth duriug the huilding and after its completiou, to prevent a trace of iron getting near it. Provisionally the work of the establishment at Pavlovsk will he specially directed to the normal observation of the meteorological elements and of terrestrial magnetism for which we possess accurate methods of observation. As soon as trustworthy methods have heen found for the constant measurements of other elements, such as atmospheric electricity, terrestrial currents, radiation of heat, the optics, and chemistry of the sun and sky, these elements will also form the objects of normal observations.

French Forest Planting.—Tbe *Revue des Eaux et Forets* gives a resume of etatistics derived from official eources, showing that in 1875 various communes in France replanted as forest rather more than 814 hectares of land. Towards this work the State contrihnted 29,054 francs in money, and seeds of plants to the value of 27,328 francs. In the same year 347 hectares were replanted hy private owners, with the assistance of a government contrihution of 13,705 francs. The works of the same nature undertaken hy the State itself in various mountainous districts of the country were on a far larger scale. At the end of the year 128,269 hectares had been taken in haud, of which 29,490 were completely stocked. The trees required for this purpose are supplied hy specially estahlished nurseries, covering altogether an area of 82 hectares, which yielded in the 12 month no less than 19,117,000 plants. It may hc in the recollection of our readers that the department of woods and forests, which formerly was attached to the Ministry of Finance, was incorporated last Decemher in the Ministry of Agriculture and Commerce.

Cement for Wood and Iron.—A foreign journal speaks of a cemeut made of oxidc of lead aud concentrated glycerine, whicb unites wood to iron with remarkahle efficiency. The compoeition is insoluhle in acide, ie unaffected by the action of heat, sete rapidly, and acquires an extraordinary hardness.

This Preverse Generation.

The *Argonaut* thinks our children have hut little of the spirit aud energy of their ancestors. The editor, eujoying a vacation in the northern part of the State, preaches the following lay sermou: Along the upper Pit and ite many trihutaries there is a magnificeut grazing country, huudreds of milcs in extent, sparsely populated, government land unoccupied, and open to pre-emption, homestead, and settlement. The land is rich, and under cultivation will produce vegetahles, grain, and all the hardier fruits. The climate is not as eevere as that of New England, New York, or the Western States. The snow is not deep in winter, and does not linger as late iu the spring as it does in the Eastern country named. Outside of these meadows and the beautiful valleys that margin the streams, the country is densely wooded with pine, cedar and spruce. All through the northern counties, embracing Shasta, Trinity, Siskiyou, Humholdt Modoc and Lasseu, there are valleys, eome larger and some smaller, many of them entirely unoccupied, where homes may he ohtained without cost or the expenditure of any other capital than that of lahor. There are level lands hordering the streams, the timber growing upon them indicating a rich soil. The waters ahound in fish; the hills abound in game. During the season all along tbe upper Sacramento and heyond Shasta the streams that empty into the ocean are filled with salmon.

The hills are eometimes abrupt and sometimes stretch away in gentle slopes, hearing evidence of their etrength and depth of soil in the splendid forests that climh to their very peaks. All these hill and mountain sides are watered with streame, rivulets and springs, so that irrigation is cheap and practical. The rainfall, as indicated hy the exnherant and almost tropical vegetation, is ahundant. If these mountains were Alps or Appenines they would be cultivated to their summits, and the region he thronged with a hardy and industrious population. It is in such mountain fastnesses that religion and liberty have made their grandest struggles. And yet this splendid reach of mountaiu and meadow, this broad hreadth of hill and valley, these margins of splendid rivers, this great wealtb of land and water, of wood and soil, lie almost unoccupied. Here and there ecattered through the wide domain, is the hut of the hunter or herdsman, and along the highways and centers of travel the more comfortable cottage of the farmer and home of the innkeeper. There are homes and farms herc in our northern counties for a million of families. There is affluence, plenty and ahundance, grain, fruit and vegetahles, comfort, ease and independence, awaiting the industrious toiler. Our fathers, half a century ago, would yoke their cattle, cover their wagons with cotton canvas, load them with wife, children, hams, hacon, maple sugar, take axes, guns and dogs, plunge out into the wilderness, and hy their labor carve out for themselves homes, lay hroad and deep the foundation of States, huild up civilization around them, and from barbarism create society. Our sons and our foreign immigrants in these degenerate days have no nerve for this pioneer work, no muscle to swing the ax, no courage to confront tbe forest, no daring to brave the dangers, and no patience to endure the hardships of a life of adventurous toil. Our hoys arc milksops—educated, nerveless, cowardly, hangers-on upon their mothers' apron-strings, petted, fondled, foolish, ruiued darlings—who expect to live upon their fathcr's earnings. They would he lawyers, doctors, politicians, adventurers, gamblers, thieves, anything hut honest workingmen. Our girls are a worthless set—becoming each year more worthless—and it is not their fault. We are educating them to become wives of rich men, playthings and ornaments of luxurious homes; and if they fail, and we fail, then God help them. Society is strewn with the wrecks, and the tempest has just hegun. In another generation or two the American-horn, will he a pitible helpless thiug. The sons of our sons, and the daughters of our daughters, will hecome ohjects of sympathy. If our nation has ever a peasantry, it will he from the American etock. The intellectual and over-educated can not conquer in the struggle against numbere and brute force. Our immigrant population no longer goes out to the hills and mountains, hut throngs the cities; prefers to live in squalid pauperism, in sickly tenement houses, to he hungry, ill clad, ignorant aud dirty, than to carve out a country home hy toil.

Hatching Silkworms Extraordinary.—An extraordinary statement is made hy *Galignani*—viz., that M. Duclaux, Professor of Sciences at Lyons, has discovered a method of hatching silkworm eggs at will. If, when the eggs are not more than two or three days old, they are ruhbed with a brush, subjected to the action of electricity, dipped for half a minute iu coucentrated sulphuric acid, or chlorohydric, nitric, acetic, or tartaric acid, they will hatch out, and, as the mulherry is in full leaf, two crops of worme are thus obtained in one eeason. Immersiou for a few secouds in water heated to 122° Fahr. is eaid to be equally efficacioue. The worms from the artificial hatching are eaid to be hardier tban those reared in the ordinary manner.

Successful Articles of Manufacture.

It is not always the most ingenious man who perfects the most useful inventions. In fact, a great many things are invented without invention, if we may use the expression. A workman finds that a slight change in construction will facilitate his operations, and makes the change which may make all the difference, whether the machine succeeds or not. Again, we often see two or more articles of manufacture in which there is a very slight difference; yet one will be in widespread use and the other only slightly known. And the cause of this has been, not so much due to the superiority of the article, as to the circumstances of its introduction to the public and the shrewdness of its introducer.

We often find an article or a machine suddenly attains great notoriety and success and becomes known in every direction. And this so quickly as to surprise every one but those who are attempting its introduction. We read of it, buy it, try it, and finally begin to wonder we cannot do without it.

And frequently this is accomplished with very little merit in the article itself. Advertising does it and nothing else. *Given*, a thing of only ordinary merit, well advertised, and success will be the result: and *given*, again, a superior article and it will not succeed unless properly introduced.

It takes the public a long time to find out what is good or what they want. They need to be told, and need to be told pretty often, too. It's the newspapers that really introduce these things by telling their readers about them every day, over and over again, until the facts are finally impressed on the readers' mind.

It takes judgment also to select the best mediums for this advertising. The local agent must patronize his local papers, and those in the large cities must take every occasion that presents itself, to present, also, the thing they desire to sell to the public. They must do it in more ways than one, and keep doing it. The money spent for printers' ink will return tenfold in time, and not very much time, either.

Note on Brass Working.—Most brass articles require filing in finishing, which is done by hand labor with ordinary float, bastard and smooth files. The brassfounder has to perform all kinds of plain, spherical and ornamental turnings, and this necessitates the use of many lathes and tools. In the lathe, too, the turner makes the screws on the goods, where required, by a kind of short-toothed steel comb, with a strong back. This comb is caused to travel backwards and forwards on the article operated upon till the screw is cut. The ordinary process of screwing by taps and dies is little used by the brassfounder. By the process of spinning, glass, china and wood knobs are attached to their brass fittings. The brass mounting is first formed like a flat saucer, into which the glass or other article is easily inserted. The articles being fixed in a lathe and set in motion, the workman applies to the thin edge of the saucer socket a certain amount of pressure by means of a burnisher; and this pressure has the effect of turning over the edges of the socket upon the glass or china. Optical lenses are often mounted in the same way. Brass lock, shutter, and other knobs are generally cast, each in two hollow pieces, and are spun together, so as to form one perfect article.

During the continuance of the Mechanics' Fair will be the very best time for residents of the country to visit the city, for then they will be able to see clearly what other workers in life have been achieving, while they have been engrossed in their daily avocations. They will recognize how much more there is in the world than they have given to it, and will be liberalized, enlarged and stimulated to an effort to keep pace with the careful progression of this age of marvels, and to add something from their store, be it little or much, to that progression.

To the most casual observer who wanders through the vast pavilion, and scans the fruits of genius, the mechanical skill, the arts and scences here illustrated, the spectacle must be of interest. So the more thoughtful lessons of value, not soon to be forgotten, will be learned; and we shall one and all of us be benefited in a greater or less degree by careful study of the display set before us to pass judgment on.

Taps.—A tap for a nut an inch deep required to be just movable upon the bolt by hand must be made a trifle larger than if it were intended to make a nut two inches deep a similar fit. This reason is that the variation in the pitch of the thread, which always occurs in hardening, is greater in a length of two inches than it is in one inch of the length of the tap.

Ink for Alcoholic Specimens.—Prof. Semper during his late visit to the United States, gave us the following recipe for a writing fluid for labels for alcoholic specimens. Use India ink dissolved in strong acetic acid; write and let it dry. It will stand for years.

The French vines are reported to be showing badly from that insect pest, the phyloxera, and other causes, in Lyons, Haut-Rhine, and other departments.

Useful Information.

New Artificial Stone. The *Journal of Chemistry* translates from a foreign authority to the effect that a German patent has been granted to Dr. Zeruikon, of Oderberg, for production of artificial stones by boiling of mixtures of mortar. The chief constituents of the stone, sand and slaked lime, are known to show great resistance to atmospheric influences. By boiling, a combination of silica and lime takes place, and the hardness of the mortar increases by the absorption of carbonic acid from the air. The specimens show throughout the hardness of good, natural sandstone; they are now about a year old, and must have gained in hardness, for shortly after casting they could still be cut with the knife. Cracks and fissures are nowhere observed, and are hardly to be expected in future, as the combination of lime and sand, under the action of hot water, is effected only at such low temperatures (between 120° and 150° C.) that a reduction of the lime hydrate to free caustic lime cannot have taken place. As regards cost of production, the price of the raw materials, 80 % to 90 % sand and 10% to 20 % slaked lime, will scarcely be higher than that of clay for bricks. The time of beating is nearly the same in both cases, but the heating for bricks requires nearly a white glow, whereas for the mortar stone it has only to be brought to 150° C.; thus there is considerable saving in fuel. The mode of forming the prism-shaped stones is similar to that of machine-made bricks, where they are pressed through a mouth-piece. All expenses of manufacture included, 100 kilograms (220 pounds) of the stones, of prismatic shape, cost about two marks (50 cents).

Unimployed Labor.—Col. Carroll D. Wright, chief of the Massachusetts State Bureau of Statistics, has recently begun an investigation which promises to be of very positive value in its bearings on the labor question in that State. He has undertaken a systematic enumeration of the unimployed laboring men of the State. By the term "unemployed" is to be understood not those thrown out of work for a few days by the temporary suspension of operations on which they are usually engaged, but those who may be said to be for a considerable duration of time without work. Canvassing by his own agents, Col. Wright has received returns from 100 places, including two of our large manufacturing centers. Should the remaining returns hold with those already received, it is probable that the completed canvass will show about 15,000 men out of employment. Of these, about one-third, say between 5,000 and 6,000, are skilled workmen, and the balance unskilled. The latter may be divided into three classes. Of the unskilled, 25 per cent. are the class who never work when they can avoid it, 50 per cent. labor more or less, and the balance are really desirous of employment. There has been but little call for out-door relief, either in this city or in the country towns, and the assessors of the latter report a very small amount of actual distress. Reports generally received indicate the diminution of the number of idle workers by the starting up of manufacturing this fall.

Russian Petroleum Resources.—Those who are laboring to develop our petroleum riches in the southern counties, will be interested to read of the rapid work which Russia is doing in the same direction. A Pennsylvanian, who went to southern Russia to put up some machinery, writes that the derricks are as thick in the developed oil territory as they were at Petroleum Center in its palmy days. He says one well flows twice a week for four hours at a time, at the rate of 10,000 barrels per day. In his own phrase, "the stream of oil running from her is as large as Hay's run; a solid stream of oil, free from gas and froth, forced into the air to a hight of 75 feet." He says the oil is allowed to flow upon the ground and collected in trenches dug to contain it. The wells are drilled and pumped in the most primitive and wasteful manner. The oil is transported in sacks made of bog skins and in rude barrels five feet long, upon carts with wheels ten feet in diameter. The indications are that this Russian oil field is as rich as Pennsylvania. At present it is cut off from a market, except by the roundabout navigation of the Volga and the Russian canals which reach St. Petersburg. But 400 miles of railroad, across the land that separates the Caspian and the Black seas, will put it within reach of every European customer to whom we now sell refined product. A pipe line could be laid down, which would carry the oil to the Black sea at such a moderate cost of transportation as to distance American transportation.

Concrete Bridges.—It would seem that a thoroughly well-constructed arch of concrete may be made absolutely stronger than a similar one of brick. This has, in fact, been proved in the case of a structure spanning an open cutting in one of the London railways. It is a flat arch of 75 feet span, and seven feet six inches rise in the center, where the concrete is three and one-half feet in thickness, increasing toward the haunches, which abut upon the concrete skewbacks. The material of which the bridge is made is formed of gravel and Portland cement, blended in the proportions of six to one, carefully laid in mass upon close boarding set upon the centering and inclosed at the sides.

Construction of Lightning Rods.—Dr. R. J. Mann lately summed up in a series of aphorisms the fundamental conditions to be observed in construction of lightning rods. We select a few of the most important from the *Popular Science Monthly*. The main stem of a copper lightning conductor should never be less than four-tenths of an inch diameter. This dimension is not sufficient for a building more than 80 feet high. Galvanized iron may be used instead of copper, but then the diameter must be greater in the ratio of 6.7 to 2.5, the conducting capacity of iron being to that of copper as 14 to 77. A galvanized iron-rope conductor should never be less than eight-tenths of an inch diameter; a galvanized iron strip should be four inches wide and one-eighth of an inch thick. A lightning rod must be continuous and unbroken from end to end. A rod need not be attached to a building by insulated astenings; metal clamps may be safely employed, provided the rod be of good conducting capacity and otherwise efficient. Above the rod must terminate in metal points, well projected into the air. These points should be multiple and perfectly sharp. The bottom of the conductor must be carried down into the earth and be connected with it by a surface contact of large extent. All large masses of metal in a building should be metallically connected with the lightning rod, except when they are liable to be occupied by people during a thunder storm; an iron balcony, for instance. In such cases it is better not to have the iron connected with the conductor, for there is some risk of persons standing on the balcony furnishing a path for the lightning to the rod.

Varnish for Basket Ware.—The following varnish for basket work is said to dry rapidly, to possess sufficient elasticity, and to be applicable with or without admixture of color: Heat 375 grains of good linseed oil on a sand bath until it becomes stringy, and a drop placed on a cold, inclined surface does not run; then add gradually 7500 grains of copal oil varnish, or any other copal varnish. As considerable effervescence takes place, a large vessel is necessary. The desired consistency is given to it, when cold, by addition of oil of turpentine.

Silveroid.—The *Iron Age* learns that Brown Bros. are about introducing to the trade a new metal called "silveroid," this name having already been registered at Washington. It has a fine texture, is susceptible of a high finish and can be supplied at much less cost than anything heretofore used as a substitute for real silver. Another point claimed in its favor is freedom from objections arising from corrosion where certain descriptions of metals have been used heretofore as table ware.

Good Health.

Prescription for Fits.

For a Fit of Passion.—Walk out in the open air. You may speak your mind to the winds without hurting anyone, or proclaiming yourself to be a simpleton. "Be not hasty in thy spirit to be angry, for anger resteth in the bosom of fools."

For a Fit of Idleness.—Count the tickings of a clock. Do this for one hour, and you will be glad to pull off your coat the next and work like a man. "Slothfulness casteth into a deep sleep, and an idle soul shall suffer hunger."

For a Fit of Extravagance and Folly.—Go to the workhouse, or speak with the ragged and wretched inmates of a jail, and you will be convinced

"Who makes his bread of briar and thorn
Must be content to lie forlorn."

"Wherefore do ye spend money for that which is not bread? and your labor for that which satisfieth not?"

For a Fit of Ambition.—Go to the churchyard and read the gravestones. They will tell you the end of man at his best estate. "For what is your life? It is even a vapor that appeareth for a little time and then vanisheth away." "Pride goeth before destruction and a haughty spirit before a fall."

For a Fit of Repining.—Look about for the halt and blind, and visit the bed-ridden, the afflicted, and the deranged; and they will make you ashamed of complaining of your light afflictions. "Wherefore doth a living man complain?"

For a Fit of Envy.—Go and see how many who keep their carriages are afflicted with rheumatism, gout, and dropsy; how many walk abroad on crutches or stay at home wrapped up in a flannel; and how many are subject to epilepsy and apoplexy. "A sound heart is the life of the flesh. Envy is the rottenness of the bones."

Poisoning by Ink.—The Rheims *Courante* says that a scholar in the Oberlahnstein high school incautiously smeared his upper lip with ink. On this lip there was a small sore, and, after some time, it began to swell. The swelling rapidly spread to the neighboring parts of the face, and attacked the inner surface of the mouth. Delirium set in after two days, followed on the fourth by death.

Notes on Tooth Powders.

The London *Chemist and Druggist* says: "Pharmacy has its fashions as well as other things, and the present prevailing mode is salicylic acid. Dr. Buch, of St. Petersburg, deprecates its adoption as a dentifrice. A short time ago there was a warning raised against the use of charcoal. It had similar dental recommendations, namely, that it was antiseptic, and that as far as cleansing was concerned, it was most effective. But the microscope pointed out that every particle of carbon, in however divided a state, was a small crystal, which, acting by attrition, was hurtful to the enamel. While charcoal, therefore, was said to be a fine saw, salicylic acid is now stated to be a solvent, and accordingly to be abjured. Dr. Ruch mentions that he was in the habit of using a solution of three parts in one thousand of salicylic acid, a lotion of such strength being fatal to bacteria. In a few weeks he felt a curious sensation in his mouth; the teeth appeared to become softer, and on the surface something gritty was detected, there being evidently a granular formation. The doctor believes this to be a salicylate of lime; if so, the use of the acid as a dentifrice should be discountenanced.

"We may here venture to allude to a preparation which, for occasional and careful use, is a valuable remedy for yellow, blackened and unsightly teeth. It consists of equal parts of finely-powdered wood charcoal, prepared chalk and cream of tartar. A few applications are sufficient to effect a decided change, followed by a wash of myrrh, eau-de-Cologne and glycerine. It is suggested as a tried remedy, to be used when wanted, not as a toilet requisite."

The Ear Fungus.—The *Pacific Medical and Surgical Reporter* condenses from an Eastern source the following points concerning the ear fungus, *Aspergillus nigricans*. There are several forms of microscopic fungi found in the human ear, but the *Aspergillus nigricans* is by far the most common. It collects in masses, adhering to the meatus and tympanum, and is commonly taken for wax and washed out. Greater irritation, however, is produced by the growth of the fungus than by the accumulation of cerumen. Its true character can be detected only by the microscope, under which it presents various forms, according to the stages of growth. The presence of wax does not promote its production, but it flourishes on all kinds of abnormal accumulation. Glycerine does not dissolve it as it does the wax of the ear. Its presence is apt to cause pain, and sometimes to induce an eczematous condition. Dr. Burnett removes it by repeated washings with dilute alcohol. He says nothing of other applications, such as salicylic acid and its compounds, which one would think better calculated to destroy the vitality of the parasite, with less irritation to the membrane of the ear.

A New Source of Lead Poisoning.—A rather serious epidemic of lead poisoning was recently discovered in the Taunton sanitary district, England, caused by the holes in millstones having been filled up with lead. The practice appears not to be confined to Great Britain. In the last number of the *Nordkist Arkiv* is a paragraph taken from a Norwegian periodical, in which it is stated that Dr. O. Johnson, of Sharpsborg, had met with an extensive endemic of gastric disorder, often accompanied with diarrhœa, for which he could find no cause in the local conditions, nor was there any evidence of contagion. The lead line on the gums was detected, and it was ascertained that the flour which the patients used had been procured from a mill, the owner of which had filled up the holes in the millstones with a mixture of white lead and glycerine. There were no cases of paralysis or brain disease, and the patients all recovered, with one exception. A similar occurrence is reported to have taken place in France from the use of lead to repair millstones.

Another "Cure" for Poison Oak.—Dr. S. A. Brown, U. S. N., states in the *Medical Record* that he has found a specific for the troublesome eruption produced by the poison oak or poison ivy (*Rhus toxicodendron*) so common in our woods. This specific he find in bromine, which he has used with unvarying success in at least 40 cases. He uses the drug dissolved in olive oil, cosmoline or glycerine, in the strength of from 10 to 20 drops of bromine to the ounce of oil, and rubs the mixture gently on the effected part three or four times a day. The bromile is so volatile that the solution should be renewed within 24 hours from its preparation. The eruption never extends after the first thorough application, and it promptly disappears within 24 hours, if the application is presisted in, and the patient is entirely cured.

Arsenic in Rubber Stoppers and Tubes.—The London *Medical Examiner* states that Herr Filhol has found that vulcanized India-rubber stoppers and tubes, used in the apparatus for testing arsenic by Schneider's test, will vitiate every experiment. Schneider's test depends on the conversion of arsenic into volatile arsenious chloride by distilling the suspected substance with sulphuric acid and sodium chloride. But when hydrachloric acid gas comes in contact with vulcanized rubber, it almost invariably extracts from it an appreciable quantity of arsenic.

MINING AND SCIENTIFIC PRESS.
